GLASGOW DENTAL HOSPITAL —The *Governors* of the Incorporated Dental Hospital, Glasgow, have obtained a site for a new building in Renfrew-street The intention is to erect and equip "the finest dental institution in the kingdom," and an appeal for £90,000 is about to be made

PROPOSED EXTENSIONS OF KING'S COLLEGE HOSPITAL.—*At the annual festival dinner* last week, at which the Duke of Connaught presided, it was stated that the plans for extension include the building of a block for 60 paying patients The 16 additional casualty beds, towards which King Edward's Fund makes a special grant, expiring next year, are always full, and cost a minimum of £3500 a year. The casualty cases last year numbered 16,000

Royal Marines during the years 1921 to 1925 for organic heart disease were as follows 1921, 111, 1922, 67, 1923, 23, 1924, 28, and 1925, 34 No figures are available for 1920 and those for 1926 are not yet available It is not known how many of these invalidings were the result of rheumatism and to ascertain the number would involve a considerable expenditure of time and labour, which would not appear to be justified

First-aid in Road Accidents

Dr VERNON DAVIES asked the Minister of Transport what steps were taken by his department for the provision of efficient first-aid on the roads of this country, and if he was satisfied, bearing in mind the increase of road accidents due to motor and other traffic, that the provision made was adequate —Colonel W ASHLEY replied I have no powers to provide first-aid outfits on the roads of the country

International Congress on Hydrophobia

Mr DAY asked the Minister of Health the names of our representatives who attended the International Congress on Hydrophobia which was summoned by the health section of the League of Nations held at Paris, together with the cost to Great Britain —Mr CHAMBERLAIN replied The Ministry of Agriculture and Fisheries was represented by Dr W H Andrews, the Medical Research Council by Captain S R Douglas, and the Ministry of Health by Dr W M Scott In addition, six representatives attended from British institutes overseas at which anti-rabic work is specially important. The only expenses entailed to the public funds were travelling and subsistence allowances on the ordinary scale for the three delegates from Great Britain

Small-pox at Hendon and Golders Green

Mr DAY asked the Minister of Health whether he could furnish the following particulars of the small-pox cases removed to hospital from Hendon to Golders Green, the sex and age of each patient, the vaccinal condition of the fatal and non-fatal cases, whether there were any special circumstances connected with the fatal cases that contributed to the fatal result, and whether the infection was originally contracted abroad —Mr CHAMBERLAIN replied Nine patients, whose homes were in the urban district of Hendon, were removed to hospital, one male and eight females One patient was eight days old and the others were aged 8, 15, 16, 21, 23, 37, 42, and 47 years respectively There were five fatal cases and I am informed that at the time of infection four of these were unvaccinated and one vaccinated Of the non-fatal cases, two were unvaccinated and two vaccinated at the time of infection The three vaccinated cases were aged 23, 42, and 47 respectively, and were all vaccinated only in infancy As regards the last part of the question, I am not aware of any special circumstances I am informed that the source of infection has not been traced

TUESDAY, MAY 24TH

Funds of the Dental Board

Mr HORE-BELISHA asked the Minister of Health how much the Dental Board had accumulated in cash and invested in securities, what it was proposed to do with this money, and what steps were being taken by the Board for the professional benefit of the 1921 dentists who supplied a large proportion of this money —Sir KINGSLEY WOOD replied As regards the first part of the question, I would refer the hon Member to the accounts of the Board which were presented to Parliament in March The real balance, including the invested general reserve fund, was £20,750 My right hon friend is informed that the main items of the Board's expenditure are grants in aid of dental schools, bursaries to dental students of limited means, and research As regards the last part of the question, the Board are not under any statutory obligation to spend their money for the benefit of any particular class, but my right hon friend is informed that since the formation of the Board bursaries awarded to sons of " dentists 1921 " have amounted to approximately £10,000 and the sum of £3,850 has been spent on lectures and demonstrations for the benefit of this class of dentists In addition, over £10,000 has been allocated to dental health propaganda and £23,000 to research " Dentists 1921 " participate in the benefit derived from expenditure in these two directions in proportion to their numbers

Vitamin Research

Mr DAY asked the Minister of Health if his attention had been drawn to a process discovered in Germany for manufacturing synthetic vitamins, and whether any research work was being undertaken by the departments or laboratories under his control to produce vitamins of this quality in Great Britain —Mr CHAMBERLAIN replied The investigations to which I believe the hon Member intends to refer are following the lines of work of fundamental importance done recently in the National Institute for Medical Research, at Hampstead, where the production of a vitamin of intense potency has been effected by the action of light upon a known chemical substance in pure form I am glad to be able to say that this country continues to take the leading position in vitamin research which it has held throughout I am informed that much important work upon the various vitamins, including that already mentioned, is in progress in various laboratories, and in large part with the support of public funds administered by the Medical Research Council

Toxic Action of Silica in Water

Mr MORRIS asked the Minister of Health if he was aware that local authorities were proposing to adopt the process of adding silicate of soda to soft water in order to prevent the solvent action of the water on lead pipes, whether this process had been investigated by the Ministry of Health, and whether, in view of the toxic action of silica under certain conditions, he would order that the use of this process be discontinued —Sir KINGSLEY WOOD replied My right hon friend is aware that this process has been adopted in a few districts, mainly on an experimental scale The quantity of silicate of soda used is so small that the proportion in the treated water is much less than that contained in many natural waters used for domestic supplies The results of the treatment are being carefully watched and, upon the information so far available, there appears to be no reason to apprehend any danger to health or any diminution in the wholesomeness of the water

Civil Population and Poison Gas

Mr CECIL WILSON asked the Prime Minister whether any decision had been come to as to the methods to be taken for the protection of the civil population against poison gas, and, if not, when such decision might be expected —*Mr BALDWIN replied* The problem of the protection of the civil population against gas attack is being closely studied both in its technical and its non-technical aspects I cannot at the present time particularise the steps taken further than to say that they are directed to securing in the first place the provision of an adequate personnel suitably equipped and trained in protective measures, and secondly, the dissemination at the proper time of full information in regard to the best methods of self-protection

Obituary.

WAREN TAY, F R C S ENG, L S A,

CONSULTING SURGEON TO THE LONDON HOSPITAL

WE regret to announce the death of Mr Waren Tay, one of the oldest Fellows of the Royal College of Surgeons of England, which occurred on May 15th at his house in Croydon He was in his eighty-fourth year and had lived much in retirement recently

Waren Tay received his medical education at the London Hospital and qualified as M R C S in 1866, proceeding to the Fellowship three years later After holding the usual resident appointments, he became assistant surgeon and ophthalmologist to the London Hospital in 1869, and was promoted to charge of beds seven years later He was an untiring hospital officer, giving his time without stint to the " London," and being at the same time surgeon to the North-Eastern Hospital for Children, the Hospital for Diseases of the Skin, Blackfriars, and the Royal London Ophthalmic Hospital He belonged to a simpler age when it was possible for the general surgeon to be at the same time a special authority in separate directions, some of which were actually being split into further departments during his lifetime During 20 years he worked largely in association with one of his immediate seniors, Jonathan Hutchinson, and like him combined with general surgery the pursuit of ophthalmology and dermatology, adding the third subject of pediatrics He wrote on all the subjects in which he specialised, although no big book came from his pen, nor was he a prominent contributor to any of the big systems of surgery or therapeutics He translated one of the volumes of Hebra's Dermatology for the New Sydenham Society, but his writings were largely confined to hospital reports, a certain number of clinical records in the medical journals, and the proceedings of learned societies whether it is not possible to get compulsory circulation of bottled and pasteurised milk ?

Sir KINGSLEY WOOD · That does not arise out of this question

Sir W LANE-MITCHELL May I ask if it is not the case that 90 per cent of the milk supplied in London now is pasteurised and bottled under the regulations of the Ministry of Health, so that the London public is fully protected ?

No answer was given

Small-pox in Scotland

Mr HARRISON asked the Secretary of State for Scotland the total number of cases of small-pox notified in Scotland for the year ending April 2nd, 1927, or nearest convenient date, and the names of the localities affected —Sir JOHN GILMOUR replied For the year ended April 2nd, 1927, there were notified in Scotland 61 cases of small-pox The only locality affected is Dundee

Insurance Act Benefits

Mr HARNEY asked the Minister of Health what was the approximate total amount paid to the insured population under the National Health Insurance Act from the date of its inception till now under the following heads sickness benefit, disablement benefit, maternity benefit, and additional treatment benefits, respectively, what was the approximate total amount of contributions received under the Act from each of the following employed contributor, employer, and the State, respectively, and what was the number of approved societies operating under the Act of Dec 31st, 1926 —Mr CHAMBERLAIN replied The particulars asked for under the National Health Insurance Act from the date of its inception under Dec 31st, 1926, are given in round figures for England and Wales in the following statement Total amount paid sickness benefit, £90,000,000, disablement benefit, £31,000,000, maternity benefit, £18,000,000, additional treatment benefits, £4,500,000 The approximate total amount of contributions received under the Act from employed contributors was £143,000,000, employers, £136,000,000, the State, £94,000,000 The number of approved societies with head offices in England and Wales at Dec 31st, 1926, was 926, including 27 societies with approximately 6440 branches

Vaccination Bill

Mr GROVES presented a Bill to amend the law relating to compulsory vaccination which was read a first time

THURSDAY, MAY 19TH

First-aid in Street Accidents

Dr VERNON DAVIES asked the Secretary of State for the Home Department what measures were taken in the metropolitan police district to see that prompt and efficient first-aid was available in the case of street accidents, and if he was satisfied that these measures were sufficient, bearing in mind the probability of a steady increase in these accidents owing to the rapid development of motor transport —Sir W JOYNSON-HICKS replied The main responsibility for the provision of first-aid (apart from facilities for removal to hospital) in case of street accidents must obviously rest with the police, and the importance of first-aid training is fully recognised Under present arrangements every recruit entering the Metropolitan Police receives instruction in first-aid and ambulance drill and is required to secure a certificate of proficiency in first-aid before his appointment as a constable can be confirmed At the present time about 90 per cent of the force possess certificates of competency, and I am not aware of any reason for thinking that the existing arrangements are in any respect insufficient

Dr DAVIES Can my right hon friend say whether the provision of this first-aid has necessitated any increase in the force itself ?

Sir W JOYNSON-HICKS It is quite impossible to say exactly where an increase in the force arises There may be a few more men, but I think on the whole there has been no actual increase because of this

Mr HARRIS Is this the most satisfactory way of dealing with this matter ? Would it not be better to deal with it through the improved motor ambulance service supplied by the London County Council ?

Sir W JOYNSON-HICKS I should be very glad if the London County Council would assist me

Children and Vaccination

Sir JOHN POWER asked the Minister of Health the number of children born in England and Wales last year, and how many of them were vaccinated —Mr CHAMBERLAIN replied The number of births registered in England and Wales last year was 694,563, but I am not at present in a position to say how many of these children have been vaccinated The corresponding figures for 1925 were births, 710,400, successfully vaccinated, 311,325

Cost of Small-pox Treatment

Mr HARRISON asked the Minister of Health the estimated cost of the treatment of the 12,922 cases of small pox notified in England and Wales during the year ending April 2nd, 1927, and the percentage of that cost borne by the Exchequer and local authorities respectively —Mr CHAMBERLAIN replied These particulars are not available, but no part of the cost of the treatment of small-pox cases falls on the Exchequer except in the case of patients arriving in this country suffering from the disease who are isolated and treated by the port sanitary authorities In such cases 50 per cent of the cost is borne by the Exchequer

Cost of Public Vaccination

Mr HARRISON asked the Minister of Health what was the estimated cost of public vaccination for small-pox during the year ending April 2nd, 1927, including the cost of preparing the vaccine —Mr CHAMBERLAIN replied The cost of public vaccination, including the cost of vaccine lymph issued from the Government Lymph Establishment, was approximately £175,000 for the financial year 1925-26, which is the last year for which particulars are at present available

Post-vaccinal Encephalitis

Mr BRIANT asked the Minister of Health when the report of the committee appointed in February, 1926, to consider the question of post-vaccinal encephalitis would be issued —Mr CHAMBERLAIN replied If the hon Member refers to the committee appointed to inquire and report, amongst other things, on the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination, the answer is that I am not yet in a position to say when the report will be issued

Substitutes for Ethyl Alcohol

Lieut -Colonel HENEAGE asked the Secretary to the Treasury whether an investigation had been made into the subject of substitutes for ethyl alcohol, and, if so, whether he is in a position to state the results —Mr R MCNEILL replied Yes, Sir My right hon friend arranged for an investigation into this subject by the departments concerned, and as a result the following conclusions have been reached (1) Purified methyl alcohol will remain within the scope of the spirit duty But no duty will be payable so far as it is used for industrial purposes and the official supervision of manufacture and duty-free use will be reduced to the minimum consistent with the safety of the revenue Moreover, provision has been made in Clause 11 (1) of the Finance Bill for the extension to methyl alcohol of an appropriate Excise allowance on the lines of that now payable on ethyl alcohol manufactured in this country and used duty-free for industrial purposes, in order to compensate for the expense involved in conforming to Excise restrictions on manufacture (2) As at present advised, it is not proposed to bring any other substance, which may be used as a substitute for ethyl alcohol, within the scope of the spirit duty It is, however, proposed in Clause 15 of the Finance Bill to take power to collect information as to the importation, manufacture, distribution, and use of the higher alcohols and to require manufacturers of these substances to register with the Customs and Excise Department

MONDAY, MAY 23RD

Small-pox at Hackney Wick

Captain GARRO-JONES asked the Minister of Health whether it had been found possible to trace the source of infection of the case of small-pox which had occurred at Hackney Wick, whether he was satisfied that local authorities had all useful powers to safeguard the population in such cases, and on what date, in the absence of further cases, the contacts and other inhabitants of Hackney Wick would be free from danger of infection from the case mentioned —Sir KINGSLEY WOOD replied The source of infection of this case has not yet been traced My right hon friend is of opinion that the local authorities have all necessary powers to safeguard the population in such cases if adequate use is made by the public of the facilities provided for free vaccination As regards the last part of the question, as further cases have occurred in this area, my right hon friend is not in a position to say when the inhabitants will be free from the danger of infection

Heart Disease in the Navy

Dr VERNON DAVIES asked the First Lord of the Admiralty if any youths under 21 years of age had been invalided out of the Navy during the past seven years for which statistics were available for heart disease, the result of rheumatism during their period of service, and, if so, how many — Lieut -Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied The numbers of officers and men under 21 years of age invalided from the Royal Navy and

UNIVERSITY OF LONDON —At a meeting of the Senate held on May 18th it was reported that the semi-general election of members of the Senate for the period 1927–31 had resulted in the following appointments amongst others By Convocation Mr W G Spencer, M S ; by the Royal College of Physicians of London, Dr J Fawcett , by the Royal College of Surgeons of England, Mr V. Warren Low, F R C S ; by the Faculty of Medicine, Lord Dawson of Penn, M D , and Mr H L Eason, M S

Mr Duncan MacCallum Blair was appointed as from August 1st, 1927, to the University Chair of Anatomy tenable at King s College He received his medical education in the University of Glasgow, where he was awarded 20 first-class certificates of merit in the various classes of the medical course and obtained the M B Ch B degrees with honours in October 1919 He served with the Royal Naval Volunteer Reserve for two years during the war In 1919 he was appointed demonstrator in the anatomy department of Glasgow University, and in March, 1922 senior demonstrator and lecturer since October, 1924, he has been lecturer in regional anatomy

Dr G S Wilson was appointed as from Oct 1st 1927, to the University Readership in Bacteriology and Immunology tenable at the London School of Hygiene and Tropical Medicine He was educated at Epsom College, King's College, London, and Charing Cross Hospital In 1916 he qualified as M R C S Eng and graduated M B , B S Lond , with distinction in medicine, surgery, midwifery, and pathology, and the gold medal in 1919 he obtained the M D Lond degree (pathology) and in 1920 became M R C P and took the D P H He gained various prizes at Charing Cross Hospital and the governors' clinical gold medal He served in the Royal Army Medical Corps from 1916–20 (during 1917 and 1918 in India) In 1919 he was appointed specialist in bacteriology at the Royal Army Medical College , in 1921 assistant in bacteriology under the Medical Research Council, and in 1923 lecturer in bacteriology in the University of Manchester Since 1925 he has been assistant director of the Public Health Laboratory, Manchester Dr Wilson has published a number of papers in THE LANCET and other journals; the latest of them will be found on p 1123 of this issue

The title of Emeritus Professor of Ophthalmic Medicine and Surgery at University College was conferred on Mr Percy Flemming

The Dunn Exhibitions in Anatomy and Physiology were awarded to Mr K M Robertson, an internal student, of St Thomas's Hospital Medical School

The following resolution was passed —

That Sir William Collins be informed that the Senate have learned with great regret of his decision not to seek reappointment on the termination of his period of office as one of the representatives of the London County Council on their body, and that they desire to place on record their high appreciation of the distinguished services which for so many years he has rendered to the University

With reference to the anonymous offer, already announced, of £10 000 towards the establishment of a chair of dietetics the Vice-Chancellor stated that Messrs A Wander, Ltd , had now intimated their desire to contribute a similar sum to the same object

The Vice-Chancellor announced that he had received from a donor, who desires to remain anonymous, an offer of £250 as a contribution towards any preliminary expenses involved in the preparation of a comprehensive plan for the development of the Bloomsbury site

University College, University of London —Three public lectures on Experimental Vital Statistics will be given at University College Gower-street, W C on June 8th 9th and 10th by Prof Raymond Pearl, director of the Institute for Biological Research, Johns Hopkins Hospital, Baltimore

RONTGEN SOCIETY —The twenty-eighth annual meeting of the American Rontgen Ray Society will be held in Montreal from Sept 20th to 23rd, under the presidency of Dr A Howard Pirie of Montreal This is the first occasion on which the Society has met outside the United States and, to acknowledge the honour paid to a British radiologist by his election to the presidency of the Society, a party of radiologists from this country is going to Montreal in September Dr G W C Kaye has been invited by the Society to give the Caldwell lecture

SOCIETY FOR THE STUDY OF INEBRIETY —At a meeting of this society to be held in the rooms of the Medical Society of London, 11, Chandos-street Cavendish-square W on Tuesday July 12th, at 4 P M , a short presidential address on the aims and work of the society will be given by Sir Arthur Newsholme, after which Dr Godfrey Carter will open a discussion on Drunkenness and its Detection particularly in regard to Blood and Urine Alcoholic Concentration as a Guide to Intoxication.

ROYAL SOCIETY OF MEDICINE —The house and library of this Society will be closed on Saturday, June 4th, and Monday, June 6th

Lieut -Colonel James Cran, P M O . British Honduras, has been appointed an official member of the Legislative Council of the Colony.

TYPHOID FEVER IN MONTREAL —It is stated that there have been nearly 1400 new cases of typhoid fever in Montreal since May 1st

Major John Penberthy, who was for many years professor of pathology and of medicine at the Royal Veterinary College, and was President of the Royal College of Veterinary Surgeons in 1897, died suddenly at Bath on May 23rd

ST BARTHOLOMEW'S HOSPITAL "FLEET-STREET WEEK"—The sum of £33,377 was raised by the "Fleet-street Week" which was held last October This sum includes all receipts from May 25th, 1926, to March 14th last The expenses were £1,061

POPLAR HOSPITAL FOR ACCIDENTS —A new children's ward was opened last week Sir Joseph Broodbank the Vice-Chancellor of the hospital, stated that its erection was necessitated by the increase of accidents to children caused by the growth of road traffic

INVALID CHILDREN'S AID ASSOCIATION —Lord Burnham presided last week at the annual meeting held at Lord Howard de Walden's house in Belgrave-square Last year over £84,000 was raised 18,000 cases were helped, and 7500 children sent away The parents contributed over £15 000 towards the cost of treating their children.

LONDON ROYAL FREE HOSPITAL —A fair in aid of the Centenary Fund of the hospital will be held on June 10th and 11th at the London School of Medicine for Women, Hunter-street, W C There will be dancing, students' entertainments, and music

A HOSPITAL GARDEN FETE —The British Charities Association, on the last three days of last week, held its third annual garden fête in aid of the voluntary hospitals, at the Royal Botanical Gardens, Regent's Park The fête was opened by the Princess Royal

AN ordinary meeting of the Circle of Scientific, Technical, and Trade Journalists will be held on Wednesday next, June 1st, in the Hall of the Institute of Journalists, Tudor-street, London, E C when a discussion will be initiated at 5 P M. on the Relations between Writer and Editor in Scientific and Technical Articles, by Sir Richard A Gregory

DENTAL CLINIC FOR CHILDREN —The secretary of the British Dental Hospital informs us that a special dental clinic for children under 5 years of age has been opened at Battersea, in conjunction with the Battersea Borough Council's maternity and child welfare scheme, providing for the dental treatment of expectant and nursing mothers The dental surgeon appointed is Mr J Rhys-Herbert.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Monday, May 30th, at 2 P M, at the Royal Waterloo Hospital, Dr A S Woodwark will give a lecture on diabetes, and on the same day, at the same hour, Mr W McK McCullagh will give a special clinical demonstration at the Samaritan Hospital for Women Both lecture and demonstration are free to members of the medical profession A series of demonstrations will take place during June at the Royal Eye Hospital the first will be given by Mr Letchworth on June 9th, at 3 P M From June 8th to 21st the Chelsea Hospital will hold one of its special courses on the diseases of women (Fee £5 5s) From June 8th to 29th the Central London Ophthalmic Hospital will hold an afternoon course, during which the clinical practice of the hospital will be open (Fee £3 3s) If desired an operative course can be arranged, for which the fee will be £5 5s From June 13th to 25th a course in diseases of children has been arranged in which several hospitals will take part This course will be under the direction of Dr Bernard Myers of the Children's Clinic, where some of the sessions will take place (Fee £2 2s) An afternoon course has been arranged at the Blackfriars Skin Hospital from June 20th to July 1st Special cases of interest will be shown on each Tuesday (Fee £1) The City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, will hold a special course from June 27th to July 9th , the practice of the hospital will be open to those enrolling (Fee £2 2s) Practical courses in anæsthetics and obstetrics can be arranged for by the Fellowship, which can also make arrangements for clinical assistantships in gynæcology The Fellowship also provides a general course of instruction at the associated hospitals, for which a separate programme is published Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole street, London, W 1

We are indebted to two of his friends for the following appreciation of Mr Tay as teacher and colleague —

"Tay was one of the hewers of wood and drawers of water in medicine Such men accumulate the materials with which others build He was a walking dictionary at the London in the 'nineties No one knew more than he about skin or tumours or syphilis or eyes, and he had seen more out-patients, there and at Blackfriars and Moorfields, than any living man His was a prodigious zeal for knowledge, without the desire, and perhaps without the power of exploiting it Tay owed his appointment on the staff to Jonathan Hutchinson, but Hutchinson owed very much to Tay, whose industry was ever at his call The younger surgeon was indeed overshadowed by the great clinical teacher, even it seemed at times to the weakening of his own initiative and judgment Such unconscious self-effacement, not uncommon among co-workers in science, imposes a heavy obligation on those that profit by it Later on he became senior surgeon to the hospital at the time when Hughlings Jackson was senior physician, and had to treat surgically the complicated brain cases which only Jackson at that time could diagnose Possibly Tay knew too much to be a great practitioner He considered every possibility, and knew how little surgery could do in pre-antiseptic days He lived alone, and was never married He was quietly independent in a small way, and fond of cycling out to a simple lodging on the Brighton road When a colleague pressed him to join in a holiday Tay always declined 'My landlady would be so disappointed if I did not go as usual for Whitsun ' That expresses the man "

Mr Tay lived for a long time in Finsbury-square He retired from the staff of the London Hospital in 1902, being duly elected consulting surgeon

THE LATE DR NEVILLE WOOD

Dr A F HURST writes No more useful drug has been introduced during the present century than liquid paraffin It is strange therefore that the obituary notice of Neville Wood, the first man in England to recommend it, should contain no mention of his invaluable contribution to therapeutics In 1906 he wrote a paper in the *West London Medical Journal* on the treatment of constipation by liquid paraffin, and it is only fair that his name should always be remembered in this connexion It is true that Randolph, of Philadelphia, had used it in the treatment of constipation as long ago as 1885, but its modern popularity dates from 1906, and Neville Wood told me that he had no knowledge of Randolph's work when he wrote his article. Neville Wood had also already used liquid paraffin for a long time when Adolf Schmidt, of Halle, mentioned the subject in a paper on agar-agar, though this paper appeared the year before Wood published his own experience

---

DONATIONS AND BEQUESTS —By the will of the late Mr James Froane, of Gotham-street, Leicester, who left £78,364, with net personalty £78,093, the testator bequeathed £2000 to the Children's Hospital in connexion with the Leicester Royal Infirmary , £2000 to the Leicester Association for the General Welfare of the Blind , £1000 to the Leicester Guild of the Crippled, £500 to the National Lifeboat Institution , and the ultimate residue of the property (estimated at over £50,000) to the Leicester Royal Infirmary —The late Mr William Hobbs Okey, J P , of Portarlington-road, Bournemouth, left, among other bequests, £500 to the Royal Victoria and West Hants Hospital, Bournemouth , £250 to the National Sunday School Union Convalescent Home, Bournemouth , and £250 to the Victoria Home for Crippled Children, Bournemouth —By will the late Viscountess Bearsted left, among other bequests, £5000 to the Building Fund of the Jewish Maternity Home, Underwood-street, Whitechapel , £500 to the West Kent General Hospital, Maidstone , £250 each to the London Hospital and Lord Mayor Treloar's Cripples' Home , and £200 to the Hospital for Women, Soho-square, W

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation on May 20th the degree of Bachelor of Medicine was conferred on the Hon C B Buckley

SOCIETY OF APOTHECARIES OF LONDON —At recent examinations the following candidates were successful in the under-mentioned subjects —

Surgery —P V Bamford, London Hosp , F W Crossley Holland, St Bart 's Hosp , P F Fanaken, St Mary's Hosp , S Goldman, London Hosp , H M de Hartog, St Mary's Hosp , G L McDermott and E H Roberts, St Bart 's Hosp , and V K Samy, Dundee

Medicine —P Brookes, London Hosp , J H Gillatt, Sheffield, A W Marsden,, Birmingham and St Thomas's Hosp , W D Neill, London Hosp , E H Roberts, St Bart 's Hosp , V K Samy, Dundee S le R Switzer, London Hosp , and T de L Walker, King's College Hosp

Forensic Medicine —T M Beattie, Leeds , P Brookes, London Hosp , J H Gillatt, Sheffield W Howard, Liverpool , A W Marsden, Birmingham and St Thomas's Hosp , E H Roberts, St Bart 's Hosp , and D D Stidston, St Mary 's Hosp

Midwifery —G Danby, Manchester , J A Fernandez, St Bart 's Hosp , A W Lassowsky Basle and Middlesex Hosp , M H Rashwan, Guy's Hosp E A Stroud, Birmingham , and L D Williams, Cardiff

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery —

P V Bamford, P Brookes, G Danby, J A Fernandez, J H Gillatt, W Howard A W Marsden, W D Neill, V K Samy, and L D Williams

ROYAL COLLEGE OF SURGEONS OF EDINBURGH — At a meeting of the College held on May 17th, Dr A Logan Turner, the President, in the chair, the 22 successful candidates, out of 44 entered, who passed the requisite examinations on Jan 7th, 1927, were admitted Fellows —

James Neilson Adam, Harold Grover Armstrong, Thomas Oswald Chenoweth, Arthur Lynton Clowes, Amos Hubert Coleman, Kenneth Alexander Gilchrist, Alexander Campbell Gillies, Prabhakar Narayan Gokhale, Norbertus David Peter de Villiers Graaff, George Milne Gray, John Fereday Hackwood, William Keith Renwick Hamilton, Brian Maurice Johns Balwant Govind Kane, John Joseph Kelly, Harry Lewis, Arthur Neil McMillan, Boddapati Tirumal Rao, Malcolm Stuart Ross, Robert Ritchie Simpson, Ahron Sourasky, and William Combe Wilson

Passed between Sept 27th and Oct 4th, 1926 Ruth Elizabeth Millar

Higher Dental Diploma —The following candidates having passed the requisite examinations received the Higher Dental Diploma William George Coventry, Clarence Victor Berry, and Edwin Priestley

The Bathgate Memorial Prize was, after a competitive Examination in Materia Medica, awarded to Chee Juay Poh and Demetrius Maurice O'Flaherty who obtained equal marks

UNIVERSITY OF BIRMINGHAM FACULTY OF MEDICINE —A lecture on Spa Treatment will be delivered on June 9th, at 4 P M , in the medical lecture theatre by Dr C W Buckley The subject will be the Action of Mineral Waters in Disorders of the Stomach and Bowels Members of the medical profession are invited to attend

OXFORD UNIVERSITY JUNIOR SCIENTIFIC CLUB — The 29th annual Boyle Lecture under the auspices of this club will be delivered on Saturday, June 4th, at 9 P M , in the hall of Balliol College by Sir Leonard Rogers, F R S , on Climate and Disease Incidence in India Forecasting Epidemics

JOURNÉES MÉDICALES DE BRUXELLES — This medical congress will be held from June 25th to 29th, under the presidency of Prof Jean Verhoogen A large number of foreign medical authorities will take part and there will be an international exhibition The Belgian railways offer reduced fares to those attending the congress, of which further particulars may be had from the secretary-general, Dr R Beckers, at 62, rue Froissart, Brussels

R A M C WAR MEMORIAL —On May 22nd, after the afternoon service, a window was dedicated in Westminster Abbey in memory of more than 7000 officers, warrant officers, non-commissioned officers, and men, who lost their lives in the late war The dedication was performed by the Dean (the Very Rev W Foxley Norris), and a guard of honour, consisting of an officer and 12 other ranks, was furnished by Regular and Territorial units of the corps Buglers sounded Last Post and Reveille and the National Anthem was sung at the end of the service The window was designed and executed in stained glass by Mr J N Comper The names it serves to commemorate are enrolled in a book to be kept in the Chapter House

Federated Malay States—Radiologist $500–25–800 a month

Foot-and-Mouth Disease Research Committee—Research O £750

Hampstead General and North West London Hospital, Haverstock-hill, N W—H S At rate of £100 Cas Surg O at Out-patient Dept At rate of £100

York Dispensary—Res M O £150

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Canterbury, Kent , Chepstow, Mon , Tarbert, Argyll , and Totnes, Devon

The Home Secretary gives notice that he is considering the appointment of an additional Medical Referee under the Workmen's Compensation Act for the districts of the Chester, and Nantwich and Crewe County Courts (Circuit No 7) Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than June 15th

The Home Secretary also gives notice that, owing to the resignation of Dr T Ferguson a vacancy has arisen for a Medical Referee under the Workmen's Compensation Act for Dumfries County (Sheriffdom of Dumfries and Galloway) Applications for the post should be addressed to the Private Secretary, Scottish Office, Whitehall, London, S W 1, and should reach him not later than June 15th

Births, Marriages, and Deaths.

BIRTHS

Braine.—On May 22nd, at Bentinck-street, W , the wife of John Carter Braine, F R.C S , of a daughter

MARRIAGES

Morrison—Collins—On May 19th, at Holy Trinity Church, Marylebone, W , Henry Morrison, M A., M D Camb , to Olive Mary Collins daughter of Maurice Collins

Parsons—Sabberton—On May 18th, at St Andrew s Church, Chesterton, Cambridge, Frank Bett Parsons M B , L R C P, M R.C S , to Elizabeth Winter, only daughter of Mr and Mrs R W Sabberton, of the Ferry House, Chesterton, Cambridge

DEATHS.

Bryce.—On Sunday, May 8th 1927, at 72, Stroud Green road, London, N John Richmond Bryce, M D , D P H , Barrister-at-Law, in his sixty sixth year

N B—*A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths*

Notes, Comments, and Abstracts.

A CRITICAL REVIEW OF SOME MEDICAL VIEWS ON BIRTH CONTROL

By C P Blacker, M R C S Eng

So recently has the subject of artificial control of conception come within the acknowledged orbit of the medical profession, and so strongly felt is the opposition to it in many quarters still, that the reader should not expect to find, in any existing work purporting to be a compendium of different opinions, anything approaching unanimity Yet, full allowances for diversities of outlook having been made, the disagreements between the various contributors to the most recently published symposium on the subject may cause some surprise, more especially as the choice of writers seems to have been restricted to those whose views on birth control range only from cautiousness to open opposition The collection of essays[1] in question, written by six medical men and two medical women, with an introduction written by Sir Thomas Horder, has been produced under the editorship of Sir James Marchant, the secretary of the National Birth Rate Commission

In his introduction, Sir Thomas Horder warns his readers not to be disappointed if they discover that the papers which follow are written " more in a spirit of scientific inquiry than to give expression to a personal conviction, still less to personal inclination " (p ix) Better would this warning have been omitted Of relevant scientific inquiry there will be found in these pages little Of expression of personal conviction there is provided more than enough Two of the contributors are committed by their religious beliefs to an attitude of hostility to birth control which renders disinterested scientific inquiry practically impossible. When one writer assails a given process which is supposed to be under investigation with every available argument, and concludes that the process in question is contrary to God's will, it is difficult to believe that collaboration is being given to disinterested scientific inquiry, and that personal convictions, still more inclinations, are being entirely eliminated

Sir Thomas Horder, " despite considerable time spent in reading the views of others, and no less time spent in thinking upon this large and important matter," finds that his own opinion persists in remaining unformulated Advocates of birth control are relegated to three groups Supporters of women's rights and labour leaders make the first two groups, while sociologists, eugenists, and patriots together constitute the third group, whose claims to be heard merit the closest attention. It is noteworthy that medical men and women are inconspicuous within this group, but the silence of the profession, it is argued, is due rather to appreciation of the difficulties which surround it than to indifference or defective training, but as regards this point Dr Letitia Fairfield, who, on page 115, observes that " the subject of contraception is not even taught in the medical schools," holds contrary views to Sir Thomas Horder Turning to the practical aspects of the question, Sir Thomas Horder, in common with Dr Crichton-Miller and Dr Buist, but in contrast to Dr Mary Scharlieb, considers abstinence an impracticable solution. Likewise is rejected as feasible restriction of intercourse to the " safe " period, on the grounds that the safety pertaining to this period is of dubious value, and that the time of a woman's low procreative power does not always synchronize with her period of high sex desire To this argument, Sir Thomas Horder says, he had seen no reference made till he read these essays In condemning the safe period, he is in agreement with Dr Buist (p 91), but in disagreement with Dr Scharlieb (p 62) and Dr Giles (p 82) Dr Crichton-Miller does not give his views on the psychological aspect of this point, which is regrettable Chemical methods of preventing conception are condemned, and, less roundly, mechanical methods also, with some inconclusive remarks upon the double bearing of birth control upon the individual in his private life, and upon organised society, the introduction comes to an end

The first paper in the book is by Dr Crichton-Miller upon " The Psychological Aspect of Contraception " Despite its title, this essay is concerned more with the ethical than with the psychological aspects The writer condemns infanticide, abortion, and coitus interruptus, and holds that abstinence, though feasible in a few, is not practicable in the majority of cases Without discussing the important question raised by other

City of London Hospital for Dis of Heart and Lungs, Victoria Park, E —H P At rate of £100 concluded that for normal people artificial birth control is not necessary, because "Nature is a sufficient teacher" (p 163) What, precisely, is here meant by "Nature," thus personified, is not made clear It would seem that by it the writer understands the sum of those processes which, in a slum area near Birmingham, are responsible for prolonging the average interval between children from 18 months to over three years The most valuable part of this paper will be found in the last three pages, in which Sir John Robertson advances interesting evidence of the demoralisation caused among young unmarried men and women in and around Birmingham, by the propaganda of firms that manufacture contraceptives Realisation, in fact, of the pernicious influence of this trade was alone responsible for persuading this writer to contribute to the book under review So harmful does he consider the wholesale distribution of contraceptives among the unmarried, that he would advocate the suppression by law of all advertisements relating to contraceptives With this important plea, the book ends

It will be seen that there is little harmony of opinion in this work There are irreconcilable differences of ethical opinion, and there are differences no less fundamental with regard to method Differences in ethical opinion are inevitable, and could only be avoided by restricting the choice of writers even more drastically than has been done by Sir James Marchant here But differences with regard to method fall into a different category These are capable of almost complete reconciliation by reference to data. Statistical evidence the book contains, but it has little bearing upon the limited medical question which confronts the practitioner who has to decide how best to advise a patient who wishes to avoid pregnancy In a book purporting to express medical opinion, it is reasonable to expect medical problems to be discussed Yet questions such as What is the exact evidence for supposing that contraceptives produce sterility? If sterility is thus produced, which contraceptive is most likely to produce it—coitus interruptus, the sheath, the douche, the quinine suppository, the lactic acid suppository, or the rubber pessary? Which of the above methods is most likely to produce psychoneurosis? How often are erosions or other genital disease caused by rubber pessaries? Which method is the most reliable, and which least? After pelvic examination by a doctor and after fitting of the pessary is the likelihood of failure, or the probability of genital disease diminished?—these and numerous other strictly medical questions, upon which all practitioners who are consulted on this matter will desire information, remain, in this book, not only unanswered but practically unraised

It may be taken as certain that this is very far from being the last word that the medical profession will have to say on birth control

PHARMACISTS AND EARLY CLOSING

THE DEPARTMENTAL COMMITTEE'S INQUIRY

EVIDENCE was given last week by Mr H J MARTIN, chairman, and Mr G A MALLINSON, secretary, of the Retail Pharmacists' Union, before the Departmental Committee appointed by the Home Secretary to inquire into the working of the Shops (Early Closing) Acts, 1920 and 1921, and to consider and report whether it is desirable that those Acts should or should not be made permanent, and, if so, whether with or without modifications

They stated that the Retail Pharmacists' Union represents the retail chemists of England and Wales and that its membership exceeds 7000 out of a possible total of approximately 8500 Membership is confined to persons, firms, and bodies corporate actually keeping open shop for the sale of medicines, &c, in accordance with the requirements of the Pharmacy Acts The membership does not include the large multiple shop chemist concerns, but it claims to cover very effectively the smaller chemists as well as those in a larger way of business The business hours of pharmacists before the introduction of compulsory early closing were exceeded by very few of the other retail trades It was a common practice, particularly in the towns and cities, for chemists' hours to be from 8 A M to 9 P M. to 10 P M every day with Saturday an hour later Even in the country districts the chemists' shop was usually the last one to close and there the general closing hour was from 8 30 P M. to 9 30 P M. In those cases where it was not possible for the proprietor to keep a qualified assistant, he obtained no relief whatever and had to be continuously on duty 13 hours per day The popular idea had been that the pharmacist lived over his premises to give the public the opportunity of obtaining medicines out of hours In fact it was absolutely necessary for the single handed pharmacist for physical reasons An outstanding result of the introduction of early closing had been the improved physical condition of both pharmacists and their assistants owing to their having opportunities for outdoor exercise and recreation Inquiries had revealed the fact that the great majority of customers realised the relief given by the shorter hours to pharmacists and had not expressed any desire that there should be a return to the old conditions The minority who had expressed other views had changed their opinion when they discovered that it was possible to obtain medicines required in cases of illness outside the statutory hours Pharmacists were in favour of a provision to deal with cases of illness, but they were of opinion that the existing exemption met the public needs

The Doctor's Evening Consultation

In reply to questions, Mr Mallinson said that pharmacists had to wait for the evening consulting hours of doctors and that meant that they were tied Closing hours of 7 or 8 P M would not suit them because the doctors did not see their evening patients till between 6 and 7 P M, and their prescriptions had to be dispensed after that Mr Martin said that there was no necessity for a later closing hour on Saturdays Doctors did not, as a rule, see many patients on Saturday nights In most towns there were a sufficient number of chemists living on their business premises to dispense medicines required after regular hours Mr Mallinson explained that if a chemist was on the National Health Insurance panel, even if he did not live on the premises, a notice was posted up showing where medicines could be obtained when the shop was closed There was no such provision if the chemist was not on the panel

Replying to further questions, Mr Martin said that doctors knew where prescriptions could be dispensed in cases of emergency They directed their patients accordingly, and it was the business of the chemist as a rule to see that the doctors understood that there was a service available

The CHAIRMAN Where the doctor's surgery hours close at 7, is there sufficient time for a member of the public to get his prescription made up before the chemist's closing hour at 8?—Yes, generally speaking

Where the surgery hours are later is there sufficient time?—Not always, it depends on circumstances

The witness added that he had never heard of any complaints that the closing hours so far as prescriptions were concerned were too early He was not aware that any complaints had been made to the Minister of Health on the subject. It was part of their duty as a national organisation to negotiate with the Ministry of Health in connexion with National Health Insurance In that connexion from time to time the question of evening surgery hours had been raised, but it had never arisen in the form of a complaint from the Ministry that insured persons were unable to get their medicines Although the shop closed at 8 P M prescriptions were accepted in the majority of cases in the same way as if the shop was open Where it happened that the doctors had later consulting hours the chemists accommodated themselves to those hours

TRANSATLANTIC FLIGHT

Two continents were thrilled early in the week by the successful flight of the young American, Capt Charles Lindbergh, from New York to Paris without alighting In a sense his journey was not such a feat of endurance as that of his predecessors, Captain J Alcock and Lieutenant A W. Brown, who made the crossing in June, 1919, for Captain Lindbergh sat in an enclosed cabin protected from the weather and removed from the intolerable roar of the screw, but the distance he traversed was nearly double that of the previous transatlantic flight, and through every minute of the 33½ hours during which he was in the air all his senses must have been alert and attentive to the slightest stimulus, for although he had for the most part favouring wind, yet he had to traverse prolonged belts of fog extending upwards from the sea to any navigable altitude Travelling alone, he was able to save the weight of a companion but even then was so hampered by the gross weight of fuel for the long non-stop journey that his initial speed was well under 100 miles an hour, although it quickened to something like 105 miles an hour at the end On the average, however, he travelled more slowly than his predecessors His exploit should perhaps be regarded less as a feat of endurance than as an almost birdlike adaptation to the medium in which he was travelling He carried with him only the simplest instruments designed and partly executed by himself, and his charts were of the simplest, while his vestibular sense was evidently better than those of his predecessors, who admitted that they were often unaware when their vertical direction was changing His sense of horizontal direction seems not to have been impaired in the least by the absence of direct vision, for his position in the fuselage made him writers of the relation that may exist between neuroses and the use of contraceptives, he does not seem to give much weight to this relation The sentence "Modern contraceptives that are both reliable and innocuous enable a young married couple to contemplate parenthood as such, and isolated from other considerations" (p 11) seems to imply that in Dr Crichton-Miller's view some modern contraceptives are both reliable and innocuous It is a pity that he did not proceed to specify which contraceptives he regarded in this light, what he considers the degree of their reliability and the conditions of their innocuousness His attitude to birth control is tolerant, and is brought into line with a philosophy of life described as a "gospel of trusteeship" Man is "entrusted" with certain powers and liberties of which he must make fullest use Contraception has enriched and at the same time endangered marital relations The perils which are opened up can only be avoided through humanity striving towards a higher level of personal idealism than now obtains Contraception has in fact rendered both more august and more precarious the "stewardship of the clean blood of the race" (p 21) The ethical outlook implied by belief in "trusteeship" in this context is irreconcilably opposed to the ethical outlook of Drs Scharlieb and Fairfield as expressed in later chapters This essay, which can best be regarded as a philosophy of birth control, is carefully and in places inspiringly written

The next contribution, from the pen of Dr Leonard Hill, is called "Fertility and its Control" Consideration of the vital statistics of this country reveals discrepancies in fertility between different classes which there are reasons for supposing may be, in part, expressions of vicissitudes in race physiology rather than consequences of birth control Poor food and hard work conduce to fertility Idleness, abundant food, and high intellectual capacity lead to sterility There is evidence that the seminiferous tubules of the testicle require exposure to alternations of temperature in order to function their best Thus monotonous warm atmospheres and overclothing may lead to lessened fertility The fecundity of animals is promoted by feeding them on food containing abundant vitamins and calcium, and by exposing them to sunlight In common with most of the other writers in this book, Dr Hill asserts that contraceptives produce permanent sterility, though no evidence is advanced by him any more than by the others to indicate which contraceptives have this effect His essay, in fact, shows that the allegation that the use of contraceptives has in any given case produced sterility, is a very difficult one to prove, seeing how much sterility seems to exist quite apart from the use of contraceptives

The third paper is written by Dame Mary Scharlieb, an uncompromising opponent of birth control She begins her essay with the statement that the problem of whether artificial prevention of conception benefits or injures those who practise it is not one that lends itself to statistical treatment Six arguments customarily advanced by birth-controllers are considered, and answers to them are propounded which vary much in the extent to which they are likely to produce conviction in the reader To normal people anxious to space their families, three pieces of advice should be given by the doctor Firstly, they should be told to restrict intercourse to the "safe" period—i e, from the seventeenth day of the inter-menstrual period until the end of this period (German figures are reproduced from another book indicating that this period is really "safe"—a view not shared by other writers in this book) Secondly, they should be advised to avail themselves of the period of lactation which is usually one of infertility Lastly, normal people should be informed "that marriage is not intended as a mere sanction of cohabitation but that it exists for the high and holy purpose of the increase of the human race for a kindly provision for the right fulfilment of God-given instincts, and also for the spiritual and moral joy of the couple" (p 61) The man or woman who will not thus practise self-restraint, who uses in fact, any form of contraceptive, is practising "*Masturbation à deux*" (p 61) The essay ends with the remark that the whole aspect and story of artificial birth control is so sordid that it is difficult to understand that anyone should be willing to advise such methods This paper is an impressive statement both of inclination and of conviction

The fourth contribution is by Dr A E Giles who holds that the best method of preventing conception is, when possible, abstinence "The next best plan is the restriction of intercourse to the times when conception is least likely to occur" (p 82) Other methods are described, but are collectively regarded as inferior to these two This essay, however, stands out in that it contains the only piece of original statistical evidence bearing upon the harmfulness of contraception which will be found in this book The figures are held to indicate that fibroids of the uterus are caused by the use of contraceptives "Of 881 cases," writes Dr Giles," in which the diagnosis of fibroid tumours was verified by operation, 271, or 30 8 per cent., occurred in single women, 176, or 20 per cent, were in childless married women The remaining 434, or 49 2 per cent, were in women who had had children but among them the average time that had elapsed since the birth of the last child was 10 years" From these figures Dr Giles considers it sound to conclude "that if *uterine congestion is frequently stimulated by married life* without the opportunity of this congestion finding its normal outlet in pregnancy, it is all the more prone to expend itself in the formation of fibroid tumours Consequently, when birth control is practised from the outset of married life, before any pregnancies have taken place, it seems certain that the practice favours the development of fibroid tumours of the womb" (pages 87 and 88) The certainty of this conclusion would appear, however, to be somewhat weakened by the fact that nearly a third of Dr Giles's cases were unmarried women in whom uterine congestion had, presumably, never been stimulated by married life As they stand, Dr Giles's figures seem to suggest that uterine fibroids are just as likely to be caused by abstinence as by the use of contraceptives.

The next essay is written by Dr A C Buist, who rejects abstinence as a method of birth control, on the grounds that it is "usually not feasible, and when it is feasible, not always harmless" (p 93) Likewise opposed are coitus interruptus, the utilisation of the "safe" period, and the practice of douching after coitus Other preferable methods are passed over with the remark that they are "described in sufficient detail in available publications" The rest of the paper is concerned with ethical, biological, and social considerations from which no definite conclusion is drawn

The sixth paper is contributed by Dr Letitia Fairfield, and is called "The State and Birth Control" Dr Fairfield, *who writes with a clarity and vigour not conspicuous in much* of the book, argues that if the Ministry of Health were to authorise local authorities to give information on contraception to whomsoever asked for it (which was the measure proposed recently in the House of Commons), two unfortunate consequences would follow The first is that maternity and child-welfare centres, which are partly supported by private subscription and partly subsidised by the Ministry of Health, would, so far as their private support is concerned, be split from top to bottom if the teaching of birth control were compulsorily made a part of their function The second difficulty consists in the impossibility of leaving to the medical man or woman in charge of the centre the decision as to whether the conditions of economic difficulty under which a given patient is living, provide justification for teaching that patient contraceptive methods This is a valuable essay, which all advocates of birth control would do well to study despite the ill-concealed dislike manifested of Neo-Malthusians and Eugenists—classed together—who are held to advocate birth control because they contemn humanity (p 129), the people alluded to on the last line but two are clearly the Neo-Malthusians and Eugenists attacked at the bottom of p 108 and the top of p 109 Medical officers of health, on the other hand, are represented as advocating birth control because they respect and love humanity (p 112) That Dr Fairfield's dislike of birth control may, in part at any rate, be inspired by theological *considerations is suggested by one* of her concluding sentences "The demand for birth control is begotten of despair in God and man, it will grow as belief in religion and the dignity of man fails, and it can only be countered by a re affirmation of belief in both" It might be commented that a contempt for humanity is not necessarily implied by the belief that human beings differ from one another in value, *and that these differences have an effect upon society*

Sir Arthur Newsholme devotes the next contribution to "Some Public Health Aspects of Birth Control" His contention, which is mainly statistical in nature, is that though the recent decline in the birth-rate has not yet produced a stationary population (our population is increasing to day at the rate approximately of 1 per cent per annum—i e, over 5000 a week), there is, so far as can be seen at present, a likelihood that the birth-rate will fall further, and that this contingency will be realised or even exceeded in a decreasing population The writer proceeds to argue that socially valuable qualities are not necessarily the monopoly of the well-to-do, but may be equally distributed throughout all social strata What differences are manifested between different classes in this matter are as likely to be the products of environmental as of hereditary processes, so that in aiming at improving the environment of the less well-to-do, we are on safer ground than in urging them to adopt birth control

The last paper is written by Sir John Robertson After some obscure reflections upon the beneficence of Nature in "stepping in" and spacing *the intervals at which* children are born into human families (p 152), *this* authority proceeds to consider the fertility rates of unskilled as compared to the artisan classes, and of urban as against rural districts The indications for the exercise of conception control are reviewed, and it is

Some Aspects
OF
INFLAMMATION AND INFECTION *

A Course of Four Lectures delivered for the University of London at Guy's Hospital on May 20th, 27th, 31st, and June 3rd, 1927,

BY E. H. KETTLE, M.D., B.S., M.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY AND BACTERIOLOGY IN THE UNIVERSITY OF WALES

LECTURES I AND II.

I PROPOSE to discuss in this short course of lectures certain aspects of inflammation and infection which scarcely seem to have received of recent years the attention due to their theoretical and practical importance. I am encouraged to do this because, as I understand them, these lectures have nothing to do with examinations or degrees and form no part of a prescribed course of study. They are as it were luxury entertainments, and I do not feel that in delivering them it is incumbent upon me to restrict myself to orthodox teaching. A good deal of what I have to say is based on fact, but much is purely speculation, and not to be accepted without close scrutiny.

Inflammation is one of the most hackneyed and well-worn subjects in the whole of pathology, yet if we accept the definition of inflammation as "the reaction of irritated and damaged tissues which still retain vitality," we must, I think, admit that our ignorance of the inflammatory process is greater than our knowledge. Similarly, though we are all familiar with the process of infection in a rough and ready way, it cannot be said that our knowledge is sufficiently great to enable us to cope successfully with the microbic diseases. The reason is not far to seek. It is not because the microbic diseases present an insoluble problem, but because they have not been studied in the best way. Since this is the first unorthodox statement I have made, it would be as well perhaps if I made my meaning clear.

THE DOMINANCE OF BACTERIOLOGY.

The last 30 or 40 years have witnessed a subtle alteration in our conceptions of disease, which has come about so gradually as almost to have escaped notice. The work of the great clinicians, among whom this school is proud to remember Bright, Addison, Hodgkin, Wilks, and Moxon linked certain morbid symptoms with definite morbid anatomical lesions; Virchow and his followers traced these lesions to the actual constituents of the tissues, the cells; the study of disease became systematised and defect of function became correlated with defect of structure. Exactly how the anatomical and histological lesions upon which the illness of the patient depended were brought about was not recognised; indeed in many forms of illness it was not possible to distinguish specific lesions. Nevertheless, it was believed in those not very distant days that disease meant some definite structural alteration in the tissues of the body. The actual cause of the change in the tissues was, as I have said, unknown, though for centuries medical opinion had coquetted with the doctrine of contagium vivum. Writing in 1546, Fallopius says:—

> "Every contagious disease spreads itself throughout the whole infected substance. Thus, in phthisis, this force of contagion is conveyed by the vapour which comes from the lungs. This vapour contains certain minute corpuscles of the blood which issue forth with the breath and are spread by the circumambient air. So they are attracted to the lungs of another, and if they then reach a suitable soil they infect it and communicate the disease."

The belief in the external agent was formally established by the work of Pasteur, Koch, and the great bacteriologists who followed them, and from that day to this attention has become more and more focused on the parasite and less and less on the host. It is hardly to be wondered at if we have a little lost our heads over microbes. The isolation of a pathogenic micro-organism in pure culture from a patient and the reproduction of the disease in an experimental animal with this isolated organism forms a fascinating piece of work, but we cannot get away from the fact that a pathogenic organism can only be pathogenic if it has a host to be pathogenic in or on. It is obviously true that if there were no tubercle bacillus there would be no consumption; on the other hand, in the absence of a suitable host, no tubercle bacillus can fulfil its destiny. Furthermore, it is possible to bring the tubercle bacillus into intimate contact with a suitable host without producing tuberculosis.

The Reaction of the Host.

Without belittling the importance of bacteriology, it must surely be admitted that in any infectious process the microbe is only part of the story, and not the most important part either. It is the reaction of the host to the presence of the microbe which constitutes the condition we have to study, and though regarded as an exercise in the science of botany the intensive study of the tubercle bacillus has great merit it will never solve the problem of tuberculosis. But for the last 30 years we have been steadily moving away from our proper objective. For example, it is extremely difficult to explain why the meningococcus, which is often enough a normal inhabitant of the perfectly healthy person's nasopharynx, should be able to cause meningitis; it is, on the other hand, fairly easy to grow the meningococcus outside the body and to study its biological properties. Hence, whilst the pathologist remains ignorant about the essential cause of cerebro-spinal meningitis, the bacteriologist can tell us all that any reasonable man can want to know about the meningococcus itself. Similarly, while ignorant of the essential pathology of pneumonia, we devote ourselves to the typing of the pneumococci. It is bad enough to shirk the real problem for the easier task, but as a matter of fact our devotion to bacteriology has really increased our difficulties. In the early days of immunology, when it seemed that the promised land was really in sight, there was every encouragement to identify shades of difference in superficially similar microbes, for antigenic properties are highly specific. But it would appear that many of these differences are of little practical moment. There are four recognised types of the tetanus bacillus, for example, and many more types of virulent diphtheria bacilli, but all tetanus bacilli produce the same toxin, which is neutralised by a single antitoxin, and the same applies to the diphtheria bacillus. For the present, I think, we might be satisfied with a simpler bacteriology in medicine, and return to the real problem. Inasmuch as the pathogenic micro-organisms produce definite lesions in the body, and are only of importance because they do this, would it not be possible to classify them according to the lesions they cause, disregarding the minor variations they exhibit in morphology and biological properties? It would of course be a rough and ready classification, and it would break down from time to time, as all classifications do, but it would at least have the virtue of focusing our attention on the really important thing, the disease. If the science of bacteriology is to achieve the great position as a science which we desire for it it must extend its boundaries. It must not remain shackled to medicine; and, as a corollary to this, pathology must emerge from the dominance of bacteriology. Among other things it is to the possibility of such a simplified pathological bacteriology that I wish to draw attention in these lectures.

THE PROCESS OF INFLAMMATION.

The process of inflammation is an extremely complex one and it varies in detail with the agent which calls it forth. In some types these variations are so pronounced that the reaction is clearly specific dependent upon the periscope to see his direction. After his continuous flight of more than 33 hours he was still so much master of the situation as to circle several times over the Paris landing station before descending on ground made dangerous by the enthusiasm of an enormous crowd. He complained somewhat of stiffness of the limbs and his eyes were reddened, but he certainly was not deaf on dismounting, an affection which his predecessors had experienced. Opportunity to satisfy an enormous thirst and ten continuous hours of sleep appear to have sufficed to wipe out the travail of his journey. While all must be sensible of the skill, courage, and endurance displayed, the exploit, so happily terminated, is hardly likely to have the bearing on the progress of civilian flying which is being claimed for it by enthusiasts. No one can believe that the heavier-than-air machine is likely to make routine journeys over seas so extensive as to be practically deserted, as far as rescues in accident are in question.

* All the lesions referred to were illustrated by lantern slides.

THE HYGIENE OF A PLEASURE STEAMER

WE were lately asked to visit the *Crested Eagle*, belonging to the General Steam Navigation Company, as she has been refitted before again taking up her daily summer trips from the Tower (9.30 A.M.) to Margate (2.30 P.M.), and return. A ship of 1150 tons, she was built by J. S. White, of Cowes, and is 300 ft. long and 68 ft. across her paddle-boxes. She draws 6½ ft., has oil-fired engines of 3500 h.p., a speed of 18½ knots, and carries 1702 passengers, whose convenience and safety has been in every way considered. The wide upper deck has a small smoking saloon, and 50 seats for over 400 passengers, each seat being available in emergency as a life-raft. The saloons on the main and lower decks are well ventilated on the plenum system by three thermotanks, which heat the air to the desired temperature; directing nozzles prevent any unpleasant draught. The large dining saloon forward has a line of great windows on each side, and two large uptakes assist the ventilation. They afford a full view of the river during meals. The grill-room below accommodates 50 people, and is kept cool by an uptake to a Boyle's ventilator on the upper deck. On the main deck, too, is the kitchen, which is very compact and has a large uptake ventilator, and also a soda fountain. Here, too, are satisfactory, well-lighted lavatories for male passengers. At the after-end is the main saloon, with *seats for 125, and at its end is the ladies' cabin*, doubled in accommodation this year, well-lighted and ventilated, and with an automatic towel supply. Below this a tea-room and a bar, with supply ventilation, and in each case three uptakes to the upper deck. All these saloons have life-belts—1800 are carried—under the seats.

The accommodation for the crew is also good and well-ventilated. Their lavatories show advance and are white-painted throughout. The w.c.'s are in white enamelled ware, but the fittings for latrine paper were broken and neglected, a douche for the firemen was unused, and the white-enamelled wash-basins were less of a credit than they would have been had a smoother surface made them more easily cleaned.

The Company is to be congratulated on the care it has devoted to the hygiene of the ship.

SYNTHALIN

DR. R. Carrasco Formiguera, director of a sanatorium for diabetics at Barcelona, has recently given an account[1] of his experiences with synthalin, a synthetic substitute for insulin, which was discovered by Dr. E. Frank, of Breslau,[2] and is said to be efficacious when administered by the mouth. Dr. Formiguera claims to be the first physician outside Germany to use this preparation, having obtained it on a special visit to that country. He describes 34 cases, and concludes that in the treatment of diabetes synthalin should prove to be a valuable adjunct to insulin, though it does not replace it except in mild cases, dietary restriction being required as well. In cases of moderate severity synthalin may make it possible to dispense with much of the insulin dosage. In severe cases complete substitution is impossible because the doses of synthalin required to control the sugar cannot be tolerated. In cases of threatening or actual coma, its slowness of action makes it almost useless. The differences in the reaction of individuals to the drug are remarkable, and intolerance was very noticeable in Dr. Formiguera's cases. Five could not tolerate synthalin at all, nine bore it badly in doses large enough to be effective, whilst 20 took it well. As a rule women show less tolerance than men. The disturbances are mainly digestive and are probably vagal in origin, Dr. Formiguera considers, as they occur equally after injection. There may be anorexia, nausea, vomiting, abdominal pains, and diarrhœa, and there is often much depression. Owing to cumulative action they may appear some time after treatment is begun. The ill-effects, he says, can sometimes be modified by giving camphor monobromide, menthol valerianate, oil of peppermint, or similar drugs, but their action is uncertain. The ill-effects with ordinary dosage as a rule disappear within 24 hours and leave no sequelæ. The existence of renal, circulatory, or digestive troubles does not appear to be a contra-indication to the use of synthalin.

LEBANON HOSPITAL FOR MENTAL DISEASES

THE twenty-eighth annual meeting was held at Friends House, Euston-road, London, on May 19th, Dr. E. W. G. Masterman, chairman of the General Committee, presiding. Dr. H. Watson Smith, who has directed the hospital for the last 17 years, personally presented his medical report. The number of patients under care during the year had risen, he said, from 230 to 308 (176 men, 132 women), the hospital being now seriously handicapped for lack of accommodation. Fifty-six patients were discharged completely recovered, and 47 improved. Among the patients many nationalities, religions, and classes were represented, from the richest to the destitute. Regular instruction in mental diseases had been given by Dr. Watson Smith to classes of students from the American University, Beyrout, and several fifth-year students (Egyptian, Syrian, and Greek) had taken resident courses of clinical study. Major J. W. Mackinnon, R.A.M.C., and Lieut.-Colonel H. G. L. Wortabet, I.M.S. (retd.), bore witness to the pressing need for this hospital in Syria, where it is still the only mental hospital, and Dr. A. J. Manasseh, of Brumana, expressed the thankfulness of Syrian medical men at having this model hospital available for their patients; the constant development in the laboratory and elsewhere astonished him at each visit. Dr. F. H. Edwards, late superintendent of Camberwell House, referred to the pioneer work of Tuke and others in substituting for imprisonment and worse—still to be seen in some countries—the good conditions and scientific treatment given to mental invalids in England to-day. The results at Asfuriyeh were excellent, partly owing to the number of acute early cases admitted. Altogether, 2877 patients had now received care and treatment there, of whom 1479 had been discharged either cured or improved. Archdeacon Beresford Potter, late of Cyprus, commended the international and interdenominational lines on which the hospital was conducted. The new report, giving the latest statistics, with tables showing kinds of insanity dealt with and occupations of the patients admitted, will be ready shortly, and can be obtained from the secretary, at 139, Marylebone-road, W. 1.

SCIENTIFIC SIMPLICITY IN PHOTOGRAPHY

UNDER this title Messrs. Burroughs, Wellcome and Co., Snow-hill Buildings, London, E.C. 1, have issued a little book showing the advantages of using "Tabloid" chemicals and containing many hints for the successful pursuit of the photographic art. The modern technique of desensitising, which to a large extent abolishes the use of the dark room, is fully and simply explained, exposure and development are dealt with at length, and there are numerous tables covering all classes of films and plates. Copies will be sent post free on application.

MAORI NAVIGATION

IN an account of an address by Dr. Peter Buck (Te Rangi Hiroa) to the Australasian Medical Congress (THE LANCET, May 7th, p. 990) it was stated that amongst the feats of Maori seamanship in the Stone Age was the voyage from Hawaii to New Zealand across some 60° of latitude. We are informed that this is incorrect and that the voyage was from Hawaiki to Tahiti, a distance of between 2000 and 3000 miles, of course with stoppages at other islands on the way.

THE LATE DR. RICHARD GRIFFITH.—At the age of 53 Dr. Richard Griffith died at Carnarvon on May 21st after a brief illness. He was the eldest son of the late Dr. Samuel Griffith and was educated at Clifton and Clare College, Cambridge. After qualifying as M.R.C.S. Eng. from the London Hospital in 1902 he settled at Portmadoc, where his father also was in practice. During the late war he held a captain's commission in the Royal Welsh Fusiliers and was present at the landing at Suvla Bay in 1915. After being wounded and invalided home he was transferred to the Royal Army Medical Corps, and served in Egypt, Mesopotamia, and Palestine. He was twice mentioned in despatches and gained the rank of brevet lieut.-colonel. Dr. Griffith, like his father, was a justice of the peace for the county of Carnarvon, and he was a medical referee for the Ministry of Pensions. He recently gave the site for a new hospital to the town of Portmadoc.

[2] THE LANCET, 1927, i., 35.

so much so, in fact, that the main facts are in danger of becoming completely obscured by a mass of detail. There is no doubt that in the future the cellular study of inflammation will prove to be of the first importance, but much work remains to be done before we shall be able to see our way clearly All I can do here is to indicate the more significant facts when discussing individual types of inflammation, though, in passing, I would note that the polynuclear leucocyte is not necessarily the earliest or the most important cell taking part in the reaction: the fixed connective tissue cells and the adventitial cells also play their part

INFLAMMATORY REACTIONS TO NON-BACTERIAL AGENTS

Although bacteria are the most important of the agents which may initiate inflammation, so much so that in our thoughts inflammation and infection are almost synonymous terms, highly instructive reactions may be brought about by other means It will not be possible to deal at all exhaustively with these non-bacterial reactions, but only to select especially two or three which have a direct application to the bacterial infections to be reviewed Moreover, even in these selected examples, only general features can be dealt with, for even the mere anatomical differences in the tissues of the various experimental animals cause variations in the lesions produced

Inflammation due to (1) *Calcium*

One of the most constant and striking of the chemical inflammations is that produced by calcium. It has been studied and clearly described by Bullock and Cramer I have mostly used mice for the study of this reaction, but have satisfied myself that calcium inflammation in other animals is comparable to that in the mouse When calcium chloride in quantities of 5–10 mg or less is injected into the subcutaneous tissues of mice an inflammatory reaction is noticeable in a few hours and fully developed in 24. Its most striking feature is an intense jelly-like œdema which extends widely and is accompanied by considerable congestion In time the œdema disappears though it may last for three days or more, but the congestion persists for considerably longer Healing takes place with the formation of vascular adhesions between the skin and the thoracic and abdominal walls. Microscopically the lesion shows, in addition to the œdema, intense dilatation of the blood-vessels with occasional hæmorrhages, and a considerable exudation of leucocytes Hyaline thrombi are often found in the dilated vessels, possibly as the result of the widespread damage to the endothelium of blood and lymph vessels Other evidence of tissue destruction is seen in the degeneration and even the necrosis of the muscle-fibres in the neighbourhood, and the skin is sometimes ulcerated The actual degree of tissue destruction, however, is scarcely appreciated till it is rendered more obvious by the subsequent process of repair The characteristic features of the reaction, then, are diffuse necrosis of tissue, varying with the intensity of the dose, pronounced congestion and an abundant inflammatory exudate of which the fluid constituent is particularly prominent In fact, the calcium reaction is apparently chiefly due to derangements of the local circulation

(2) *Silica*

An even more striking inflammatory process is that produced by silica If this substance is injected into the subcutaneous tissues of mice a sequence of changes occurs which progresses for several days Gye and Purdy have shown that silica is primarily an endothelial poison, but in concentrated doses of 5–10 mg the vascular effect is not nearly as pronounced as with calcium The lesion is primarily a destructive one, consisting of a coagulation necrosis of the tissue and the serum poured into it Within a few hours of the injection it can be recognised as a zone of necrosis, quite acellular, except for a few leucocytes at the periphery Beyond it for some distance the capillaries are dilated and engorged and present active margination and emigration of leucocytes. These polymorph leucocytes surround the necrotic zone, forming a dense band of cells which become necrosed themselves Within three days a lesion is produced, so characteristic as to be specific. It consists of a central necrotic area surrounded by a zone of leucocytes, most of which are themselves undergoing destruction Outside this there is a secondary area of necrosis, which is bounded by granulation tissue In course of time the lesion inspissates and becomes invaded by macrophages, and the final picture is that of an organising inflammatory fibrosis

The extent of the silica lesion naturally depends on the dose administered, but it always tends to be strictly localised in contrast to the widespread effect of the calcium lesion The reaction brought about by different forms of silicon, is, as I shall hope to show, a matter of considerable practical importance.

(3) *Turpentine*

Turpentine causes a local inflammation which appears to combine to some extent the features of the calcium and the silica lesions In addition to a pronounced vascular reaction, it causes tissue necrosis and a most intense accumulation of leucocytes The abscess then formed spreads by the death and solution of the leucocytes and the determination of fresh cells to the part The removal of the irritant must be a slow process, for tissue destruction continues for a considerable time, and the extent of the lesion, when compared with that produced by calcium and silica, is out of all proportion to the amount of the poison administered. Healing is naturally slow, and when it is finally achieved, is accompanied by a pronounced degree of scarring

(4) *Inert and Insoluble Substances*

Certain inert and insoluble substances also produce easily recognisable lesions in the tissues A feature common to most of them is the foreign body giant cell, a syncytial mass which surrounds the foreign substance All who have had much experience of surgical pathology must have seen many instances of this reaction around ligatures embedded in the tissues Cholesterin, as Matthew Stewart has shown, is another common cause of the foreign body type of reaction, and rather similar lesions may be produced experimentally by aluminium oxide

INFLAMMATORY REACTIONS PRODUCED BY MICRO-ORGANISMS

Tissue Predilections

Turning now to the inflammatory reactions produced by micro-organisms, the partiality of certain organisms for certain tissues is well recognised The staphylococcus is the common infecting organism in the acute lesions of the skin and in osteomyelitis; the pneumococcus affects the lung; Pfeiffer's bacillus attacks particularly the mucous membrane of the respiratory passages, as also does the diphtheria bacillus. One of the most striking examples is the distribution of the three main types of meningitis—the streptococcal and pneumococcal, the meningococcal, and the tuberculous Equally remarkable is the localisation of the typhoid bacillus in the lymph follicles of the intestine And many other examples could be quoted. Sometimes, it is true, other factors than those specific to the organism determine the localisation of an infection. *Gas* gangrene, for example, is a disease of muscle because it is only in muscles that the organisms are able, as a rule, to develop, not because they prefer muscles to other tissues; the localisation of the *disease is determined* by mechanical factors Again, the atypical distribution of organisms in the body is quite common; the gonococcus and Pfeiffer's bacillus may cause ulcerative endocarditis, and the typhoid bacillus periostitis But, broadly speaking, the rule holds good; there is a definite determination of certain organisms to certain tissues. It is possible to talk of the organisms of *osteomyelitis*, of anterior and

and easily recognisable as due to some special agent Others have so many features in common that it is only with great difficulty that one type can be distinguished from another, and before we can hope to analyse the mass of lesions with which we are confronted, it is necessary to appreciate what are the basal features of the process In every text-book of pathology chapters are devoted to inflammation in general and I do not propose to cover the ground again at all formally, nor to enter into such sterile controversies as to whether repair should be included as part of the process. and whether the name should be reserved for purely local reactions It is useful to recognise four inflammatory stages the initial injury, the immediate vascular reaction, the exudation, and the stage of repair These stages, of course, pass insensibly one into the other and they may be, and frequently are, coexistent, on the other hand, they may vary considerably in intensity and are at times so slight and transient as scarcely to be recognisable The actual initiation of the process may be due to innumerable causes, simple trauma, metabolic products, products of cell disintegration, chemical and physical agents, and micro-organisms may all lead to a chain of recognisable reactions But exactly how any one of these agents acts is a matter difficult to determine, it is, indeed, the great problem of infection It is rarely possible even to be certain that a single cause is operative at any one time, the majority of inflammatory reactions are due to or are aggravated by more than one cause Bacterial infections, for example, are accompanied in the earliest stages by cell destruction, and the course of the reaction is profoundly modified thereby There is ample evidence to show that the simple presence of an organism, though it must necessarily be followed by an inflammatory reaction, however mild and transient, need not give rise to clinical infection, but infection occurs, probably with much greater frequency than we are aware, when the process is modified by another factor favourable to the organism The carrier problem is explicable only in this way, as is also auto-infection The importance of accessory factors will become clear when we have occasion to discuss experimental infection.

The Vascular Changes

The cardinal signs of inflammation, redness, swelling, and heat, are so obviously associated with local alterations in the blood-supply of the part affected that it is little to be wondered at if the vascular changes in inflammation have occupied a dominant place in pathological teaching Though, as Prof William Bulloch has reminded us, to two Englishmen, Augustus Volnay Waller and William Addison, belongs the credit of having first described what happens in the blood-vessel of inflamed tissue, it is from the classical work of Cohnheim that our knowledge of this aspect of inflammation is derived The sequence of changes as they occur in semi-transparent tissues such as the tongue or the mesentery of the frog have been described by him for all time, and it behoves all students of pathology to repeat at least once in their lives his observations By no other method can the dilatation of the vessels the primary acceleration and later retardation of the blood flow, the margination and emigration of the leucocytes, and the final stagnation of the current, be appreciated so strikingly But having once performed this dramatic experiment, the student may revert with more profit to ordinary fixed and stained histological material

For Cohnheim the whole story of inflammation could be read in the blood-vessels He writes "inflammation is the expression and consequence of a molecular alteration in the vessel walls", and so great was the weight of his authority that for years his teaching was widely accepted There has later been a tendency for the pendulum to swing rather too far in the other direction We know that the vascular changes are not the essential feature in inflammation The classical researches of Metchnikoff and his school established the fundamental nature of the cellular reaction in the lower animals In the higher animals inflammation may occur in non-vascular tissues, and even in tissues with a rich circulation the vascular changes vary in degree and in time of onset Krogh, for example, has drawn attention to the characteristic lag in the vascular reactions in inflammation brought about by light and by abrin, and there can be no doubt that in many inflammations tissue changes are in progress before any alteration occurs in the blood-vessels Nevertheless, the vascular reactions on which depends the exudation of fluids and cells are highly important in modifying the inflammatory process, and, as I shall hope to show, the specific nature of the response to many injurious agents is determined by the changes occurring in the vessels of the part As to the mechanism of the vascular dilatation, the exudation of fluid, and the alteration in the rate of blood flow, there is much yet to be explained, though of recent years a good deal of light has been thrown on the subject. From the descriptions in many text-books one might form the opinion that the flushing of the inflamed part with blood and the outpouring of large quantities of lymph were invariably beneficial processes, were, in fact, intelligent responses on the part of the tissues of the organism As a matter fact, they are nothing of the kind. They do not depend at all on nervous influences, but are local reactions to local injuries They are, as Cohnheim said, manifestations of a molecular alteration in the vessel wall From the work of Krogh and his colleagues, we know that the capillaries are actively contractile tubes, which respond by dilatation or contraction to different stimuli Also, we know that the passage of fluid from the capillaries is greatly increased when they are dilated The dilatation of the arterioles, the capillaries, and the veins is due to the paralysis of the contractile elements of their walls, and the degree of engorgement in inflammation depends upon the nature of the agent producing the inflammation, its concentration, and its diffusibility It is interesting and important to note that products of protein degradation are capable of producing vaso-dilatation, for this may explain the delayed engorgement occurring in certain reactions, and it enables us to appreciate how multiple factors may be concerned in an inflammatory process. The determination of leucocytes to the part is nearly always beneficial, especially in the microbic infections, but even this expression of activity may be ill-advised, for the presence of phagocytes may not only determine an infection, but may also contribute to its generalisation It has been believed, for example, that the development of tetanus in experimental animals after the injection of tetanus spores combined with other substances is due to an inhibition of phagocytosis In some unpublished work carried out some years ago, Dr W E Gye and I found that tetanus can develop in spite of the most remarkable accumulation of leucocytes and the most intense phagocytosis There is in other directions plenty of evidence to show that phagocytosis by no means necessarily implies the death of the phagocytosed organism The fluid of the exudate also acts beneficially in the majority of cases, but again I wish to insist that it is not poured out as part of an intelligent attempt to combat the infection It is forthcoming because of certain alterations brought about in the tissues and vessels of the part by the agent which initiates the process The intensity of the œdema and the characters of the fluid must necessarily vary with the agent in question, In anthrax, for example, the characteristic feature of the lesion is the intense inflammatory œdema but with avirulent strains of this organism the fluid part of the exudate is diminished, whereas the cellular constituents are notably increased Later I shall bring forward evidence to show that an inflammatory œdema artificially produced may affect an infectious process very adversely

I shall not attempt to enter into any discussion about the types and origin of the cells of the inflammatory exudate—the literature of this subject is immense so much so, in fact, that the main facts are in danger of becoming completely obscured by a mass of detail There is no doubt that in the future the cellular study of inflammation will prove to be of the first importance, but much work remains to be done before we shall be able to see our way clearly All I can do here is to indicate the more significant facts when discussing individual types of inflammation, though, in passing, I would note that the polynuclear leucocyte is not necessarily the earliest or the most important cell taking part in the reaction , the fixed connective tissue cells and the adventitial cells also play their part

INFLAMMATORY REACTIONS TO NON-BACTERIAL AGENTS

Although bacteria are the most important of the agents which may initiate inflammation, so much so that in our thoughts inflammation and infection are almost synonymous terms, highly instructive reactions may be brought about by other means It will not be possible to deal at all exhaustively with these non-bacterial reactions, but only to select especially two or three which have a direct application to the bacterial infections to be reviewed Moreover, even in these selected examples, only general features can be dealt with, for even the mere anatomical differences in the tissues of the various experimental animals cause variations in the lesions produced

Inflammation due to (1) Calcium

One of the most constant and striking of the chemical inflammations is that produced by calcium It has been studied and clearly described by Bullock and Cramer I have mostly used mice for the study of this reaction, but have satisfied myself that calcium inflammation in other animals is comparable to that in the mouse When calcium chloride in quantities of 5–10 mg or less is injected into the subcutaneous tissues of mice an inflammatory reaction is noticeable in a few hours and fully developed in 24 Its most striking feature is an intense jelly-like œdema which extends widely and is accompanied by considerable congestion In time the œdema disappears, though it may last for three days or more, but the congestion persists for considerably longer Healing takes place with the formation of vascular adhesions between the skin and the thoracic and abdominal walls Microscopically the lesion shows, in addition to the œdema, intense dilatation of the blood-vessels with occasional hæmorrhages, and a considerable exudation of leucocytes Hyaline thrombi are often found in the dilated vessels, possibly as the result of the widespread damage to the endothelium of blood and lymph vessels. Other evidence of tissue destruction is seen in the degeneration and even the necrosis of the muscle-fibres in the neighbourhood, and the skin is sometimes ulcerated The actual degree of tissue destruction, however, is scarcely appreciated till it is rendered more obvious by the subsequent process of repair The characteristic features of the reaction, then, are diffuse necrosis of tissue, varying with the intensity of the dose, pronounced congestion and an abundant inflammatory exudate of which the fluid constituent is particularly prominent In fact, the calcium reaction is apparently chiefly due to derangements of the local circulation

(2) *Silica*

An even more striking inflammatory process is that produced by silica If this substance is injected into the subcutaneous tissues of mice a sequence of changes occurs which progresses for several days Gye and Purdy have shown that silica is primarily an endothelial poison, but in concentrated doses of 5–10 mg the vascular effect is not nearly as pronounced as with calcium. The lesion is primarily a destructive one, consisting of a coagulation necrosis of the tissue and the serum poured into it Within a few hours of the injection it can be recognised as a zone of necrosis, quite acellular, except for a few leucocytes at the periphery Beyond it for some distance the capillaries are dilated and engorged and present active margination and emigration of leucocytes. These polymorph leucocytes surround the necrotic zone, forming a dense band of cells which become necrosed themselves Within three days a lesion is produced, so characteristic as to be specific It consists of a central necrotic area surrounded by a zone of leucocytes, most of which are themselves undergoing destruction Outside this there is a secondary area of necrosis, which is bounded by granulation tissue In course of time the lesion inspissates and becomes invaded by macrophages, and the final picture is that of an organising inflammatory fibrosis

The extent of the silica lesion naturally depends on the dose administered, but it always tends to be strictly localised in contrast to the widespread effect of the calcium lesion The reaction brought about by different forms of silicon, is, as I shall hope to show, a matter of considerable practical importance

(3) *Turpentine*

Turpentine causes a local inflammation which appears to combine to some extent the features of the calcium and the silica lesions In addition to a pronounced vascular reaction, it causes tissue necrosis and a most intense accumulation of leucocytes The abscess then formed spreads by the death and solution of the leucocytes and the determination of fresh cells to the part The removal of the irritant must be a slow process, for tissue destruction continues for a considerable time, and the extent of the lesion, when compared with that produced by calcium and silica, is out of all proportion to the amount of the poison administered. Healing is naturally slow, and when it is finally achieved, is accompanied by a pronounced degree of scarring.

(4) *Inert and Insoluble Substances*

Certain inert and insoluble substances also produce easily recognisable lesions in the tissues A feature common to most of them is the foreign body giant cell, a syncytial mass which surrounds the foreign substance All who have had much experience of surgical pathology must have seen many instances of this reaction around ligatures embedded in the tissues Cholesterin, as Matthew Stewart has shown, is another common cause of the foreign body type of reaction, and rather similar lesions may be produced experimentally by aluminium oxide

INFLAMMATORY REACTIONS PRODUCED BY MICRO-ORGANISMS

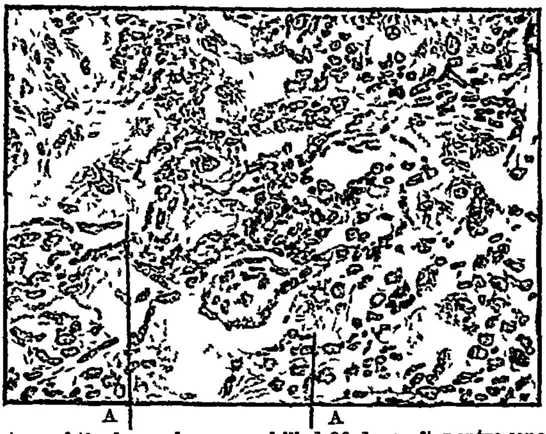
Tissue Predilections

Turning now to the inflammatory reactions produced by micro-organisms, the partiality of certain organisms for certain tissues is well recognised The staphylococcus is the common infecting organism in the acute lesions of the skin and in osteomyelites, the pneumococcus affects the lung; Pfeiffer's bacillus attacks particularly the mucous membrane of the respiratory passages, as also does the diphtheria bacillus One of the most striking examples is the distribution of the three main types of meningitis—the streptococcal and pneumococcal, the meningococcal, and the tuberculous Equally remarkable is the localisation of the typhoid bacillus in the lymph follicles of the intestine And many other examples could be quoted. Sometimes, it is true, other factors than those specific to the organism determine the localisation of an infection Gas gangrene, for example, is a disease of muscle because it is only in muscles that the organisms are able, as a rule, to develop, not because they prefer muscles to other tissues; the localisation of the disease is determined by mechanical factors Again, the atypical distribution of organisms in the body is quite common , the gonococcus and Pfeiffer's bacillus may cause ulcerative endocarditis, and the typhoid bacillus periostitis But, broadly speaking, the rule holds good , there is a definite determination of certain organisms to certain tissues It is possible to talk of the organisms of osteomyelitis of anterior and posterior basal meningitis, of fibrinous pneumonia, of membranous croup, and so forth. And—and this is the important point—nine times out of ten we shall be talking of a specific organism.

Specific Histological Lesions

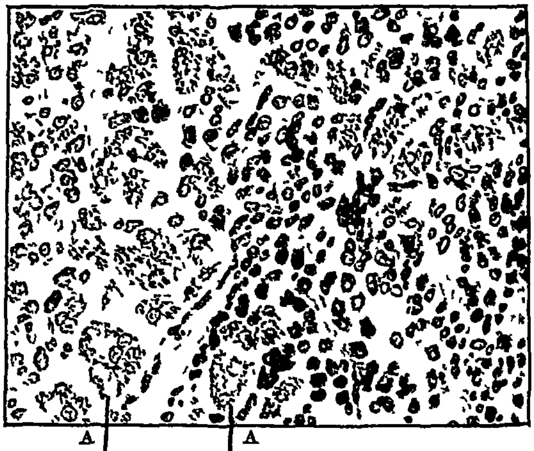
If it is possible to classify organisms in this rough-and-ready way along purely anatomical lines, it is much easier to do so by resorting to histology. The tubercle bacillus characteristically attacks the lungs, and so well recognised are the pulmonary lesions it produces that there is seldom any difficulty in distinguishing them from those brought about by other organisms. But the tubercle bacillus also attacks the skin, the bones and joints, the alimentary canal, lymphadenoid tissue, the genito-urinary system and serous membranes. Indeed, so catholic are its tastes that it defeats any attempt to force its lesions into an anatomical classification. Microscopically, however, the lesions it produces in the tissues are almost pathognomonic. They vary, of course, between cell destruction on the one hand and cell proliferation on the other, but the fundamental tissue changes brought about by the tubercle bacillus are so characteristic that the presence of the organism can nearly always be diagnosed from a microscopic examination of the lesion. Further, it does not matter what type of tubercle bacillus it is, the essential lesions are the same whether they are caused by the bovine or the human type of organism. One may even go further and recognise a type of tissue reaction brought about by the pathogenic members of the great acid-fast group of bacilli, for the lesions of leprosy, though easily distinguishable, are essentially very much like those of tuberculosis. Such differences as exist seem to be due much more to a greater virulence of the tubercle bacillus than to fundamental differences between the organisms. An even more striking illustration of this conception is seen in the organisms pathogenic in the intestinal tract. Morphologically the various Gram-negative non-lactose fermenting bacilli are very much alike, and though some of them are easily distinguished from one another by cultural tests, attempts at a still finer differentiation have landed us in rather a difficult position. If, however, we resort to a pathological diagnosis, it becomes apparent that we have to deal with two main groups, the typhoid and the dysenteric. It is, I think, extremely important that organisms so closely allied morphologically and culturally as the typhoid and the dysentery bacilli should produce such different lesions. It is surely more significant that organisms so closely resembling each other should cause diametrically opposite reactions in the tissues of the host than that organisms giving rise to essentially the same changes in the intestine should exhibit minor serological and cultural differences. I do not wish to minimise in any way the importance of bacteriological observations in these diseases. Inasmuch as most of the patients survive their infections, and their lesions never come under observation at all, accurate diagnoses can only be made with the help of the bacteriologist, and from the epidemiological and public health points of view an accurate bacteriological diagnosis is of the first importance. But a true understanding of a disease with, it may be hoped, the development of rational methods of combating it can only be arrived at by the study of the disease process, and it is for this reason that one would be glad to see at least as much attention devoted to the lesion as is lavished upon the microbe.

FIG 1.



Section of the lung of a mouse killed 90 days after intravenous inoculation with human tubercle bacilli. Note the persistence of bacilli in the macrophages (A) and the absence of necrosis or inflammatory reaction.

FIG 2



Section of a human spleen from a case of leprosy. Note the presence of bacilli in the macrophages (A) and the same absence of necrosis or inflammatory reaction as is seen in Fig 1.

LESIONS ATTRIBUTABLE TO VARIOUS ORGANISMS

Pyogenic Cocci.

An exhaustive dissertation on pathological histology would be wearisome, even if justified by accurate knowledge, and I am only too well aware that my appreciation of the differences in the various bacterial inflammations is still superficial. Still less do I know what these differences may mean. Some features, however, may prove to be significant, and to these attention should be directed.

It is unfortunate from our point of view that the lesions of the pyogenic cocci, the staphylococci, and streptococci, which are responsible for such a high proportion of infections, should be so difficult to analyse. They both give rise to acute reactions characterised by the typical vascular changes and the accumulation of vast quantities of polynuclear leucocytes, and more often than not it is impossible to distinguish histologically a staphylococcal lesion from one due to a streptococcus, though the anatomical distribution of the disease may be of some guidance. For the most part the staphylococcal lesions tend to remain more localised than the streptococcal. The organisms are not distributed so diffusely through the lesion, but tend to accumulate in the centre. There is a pronounced determination of leucocytes to the affected area, and the abscess then formed tends to enlarge by the death and solution of the older cells and the peripheral accumulation of new comers. In favourable cases the organisms die and the lesions are healed in the usual way by solution and phagocytosis of the pus and the activity of peripheral granulation tissue. The streptococcus tends to affect mucous membranes, and the lesions it produces are much more variable. As a rule the exudate contains more fluid and there is less tendency to localisation. The organisms tend to spread widely through the tissues, especially in lymphatic spaces, and the whole process is usually more rapid A remarkable reaction is that seen in erysipelas, when an intense infiltration of the tissues with cocci is accompanied by much fluid exudate in the looser tissue, and an accumulation of mononuclear cells rather than polynuclear leucocytes I can say little of the numerous reactions supposed to be due to variants of the *S viridans*, but the type of endocarditis due to streptococci has remarkable features (vide infra)

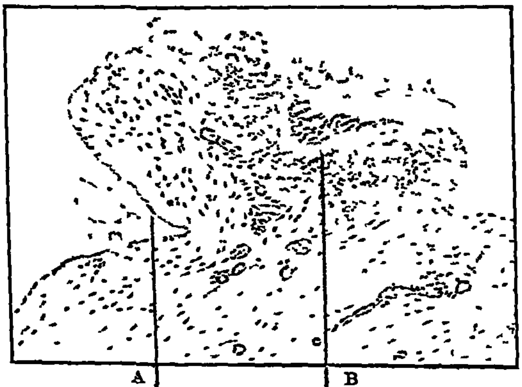
The Pneumococcus

The pneumococcus gives rise to its most characteristic lesions in the lung The macroscopic appearance of the pneumococcal pneumonia is highly distinctive, and microscopically the lesions are as easily recognisable The vascular reaction is as pronounced as in the streptococcal and staphylococcal lesions, but the typical feature is the outpouring of an abundant fluid exudate extremely rich in coagulable protein The names croupous and fibrinous pneumonia are, of course, an expression of this peculiarity In the early stages of the disease the pulmonary alveoli become filled with a meshwork of fibrin in which are entangled the cells of the exudate, red blood corpuscles, polymorphs, and also mononuclear cells, and later on, although the wandering cells become a more conspicuous part of the reaction, the fibrin is always prominent In extra pulmonary lesions the reaction may be modified, though it is always characteristic in pneumococcal infections of the serous membranes And although a fibrinous exudate occurs in other infections, it is so particularly characteristic of the pneumococcal lesions as to place them in a distinct histological class

Gonococcus and Meningococcus

Two other micrococci, the gonococcus and the meningococcus, must be mentioned, because in their reactions phagocytosis plays such a prominent and significant part Phagocytosis of the causative organisms by the cells of the exudate is, of course, a commonplace in many infections, but in these two infections it is unusually obvious In the later stages of both these diseases many of the organisms are free in the exudate, but in the early stages they are nearly all intracellular The characteristic feature is that they are not universally distributed throughout the cells of the exudate, but are limited to occasional cells in which they occur in large numbers It is impossible to avoid the conclusion that the organisms are actually proliferating within the bodies of the phagocytes Phagocytosis in these diseases would appear to be less of a defensive mechanism than an aid to infection. It may explain how the meningococci pass from the throat to the meninges And it is quite possible that the deposition of gonococci by phagocytes in the submucous tissue of the urethra may determine the chronic inflammatory changes which result in the formation of strictures

FIG 3

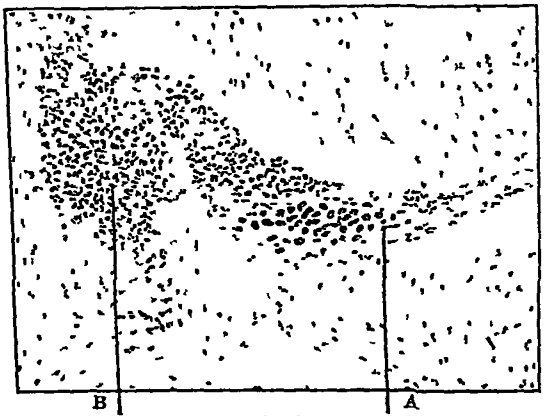


Section of heart valve showing a rheumatic endocarditis with a simple vegetation (A) and a superimposed streptococcal infection (B)

Diphtheria Bacillus

The diphtheria bacillus is not the only organism, or, indeed, the only irritant which can cause a membranous inflammation of mucous membranes, but the reactions it calls forth are highly characteristic and, in established lesions, can scarcely be mistaken for anything else In the early stages of the infection there is necrosis of the cells of the covering epithelium and pronounced vascular reaction, with the outpouring of large quantities of coagulable fluid exudate Many leucocytes appear at first, but they tend to undergo necrosis, and in the later lesions the exudate contains few cells In the fully developed lesion the mucosa is entirely necrotic and replaced by a thick inflammatory membrane consisting of coagulated protein and containing few cells The surface of the membrane is covered with large numbers of the bacilli, but these are quite superficial and do not penetrate into the deeper tissues Beneath the exudate the submucosa is intensely congested, œdematous, and infiltrated with moderate numbers of leucocytes

FIG 4



Section of human heart muscle showing an Aschoff node (A), together with an acute abscess (B) From the case of subacute infective endocarditis superimposed on acute rheumatism shown in Fig 3

Anthrax Bacillus

Anthrax is another infection in which the initial lesion has characteristic features depending on the type of inflammatory reaction called forth The vascular reaction is pronounced, there is an abundant accumulation of leucocytes, and, above all, a pronounced exudate of serous fluid which passes into the epithelium and causes the typical ring of blisters Unlike the diphtheritic or pneumococcal exudate, this fluid shows little tendency to coagulation, and fibrin formation is not a characteristic feature of the anthrax lesion The bacilli are present in numbers throughout the lesion, and though even in the advancing zone there are plenty of leucocytes, phagocytosis is not, *in my experience, a prominent feature* In the older part of the lesion, where there is much necrosis and vast numbers of leucocytes accumulate, there is, it is true, considerable phagocytosis, but it seems to have no influence on the infection, and it would appear that the intense serous exudate prevents any limitation of the bacterial growth

Anaerobic Bacilli

A group of organisms which cause highly specific lesions are the anaerobic bacilli, *B welchii*, *B œdematiens*, and *V septique*, the bacilli of gas gangrene Although at one time it was thought that these bacilli had a specific action on muscle, this does not appear to be true These organisms thrive best in deep, penetrating wounds, and in the limbs such wounds involve muscle Wounds of the abdominal and thoracic viscera are either fatal or receive operative treatment from considerations other than the occurrence of gas gangrene, but were these organs of less immediate importance to the life of the individual, there is no reason to suppose that the incidence of gas gangrene would not be as high in them as in wound of muscle

The characteristic lesion of the gas gangrene bacilli is necrosis, brought about by their toxins The tissues affected pass through the stages of cloudy swelling to coagulation necrosis and solution with the formation of gas The most highly organised tissues are affected first, but eventually the blood-vessels and connective tissues are also destroyed The organisms are present in enormous numbers in the connective tissue, and do not invade the other structures, except perhaps when necrosis is far advanced In an infected muscle they tend to remain within the limits of the epimysium, and they extend to neighbouring muscles by spreading in the subcutaneous tissue or in the deep connective tissue trabeculæ The most striking feature of the lesion is the entire lack of any inflammatory reaction The tissues are absolutely quiescent, and though there is some slight serous exudate, wandering cells are entirely absent In the cutaneous and subcutaneous tissues there may be an abundant exudate of polynuclear leucocytes which are actively phagocytic, but there is nothing of this kind in the muscles or viscera In human material I have never been able to demonstrate any differences between the reactions of these three bacilli, but J McIntosh has published beautiful figures showing that in the guinea-pig it is possible to distinguish the infecting organism from the naked-eye appearance of the lesion

Streptothrix.

As a rough and ready rule one regards as acute inflammations those in which the cellular exudate consists of polynuclear leucocytes, and chronic inflammations those in which the mononuclear elements predominate The streptothrix infections form an interesting exception to this rule In actinomycosis the fungus causes necrosis of tissue and an abundant exudation of polynuclear leucocytes, which surround the tangled masses of the mycelium But instead of a large confluent abscess, such as one sees, for example, in amœbic infections of the liver, each small focus becomes surrounded by active granulation tissue, which in turn is enclosed in dense connective tissue The foci enlarge and ramify by solution of the tissues, but destruction is always accompanied by the peripheral fibrosis, and in this way the characteristic honeycomb lesions are produced Although the disease is extremely chronic, the mononuclear-celled reaction that is seen in tuberculosis or syphilis does not occur And even in old foci, in which the mycelium is for the most part dead, there is complete absence of the giant cell phagocytes which might be expected.

Typhoid and Dysentery

In their morphology and in their biological properties the bacilli of the typhoid and the dysentery groups are so alike that one would expect them to cause lesions of a similar nature But, on the contrary, they differ in their effects on the tissues about as widely as they possibly can The dysentery bacilli attack primarily the intestinal mucosa and give rise to a diphtheroid exudate with widespread ulceration and destruction of the mucous membrane There is intense vascular reaction in the submucosa, but the condition is more or less localised to the intestine, there is no septicæmia and no involvement of the spleen The bacilli of the typhoid group, on the other hand, affect primarily lymphadenoid tissue The organisms become septicæmic and lesions occur in the skin and other organs, but the brunt of the infection falls on the lymphadenoid tissue of the intestine, the spleen, and the mesenteric glands The intestinal ulcers are not due to direct involvement of the mucous membrane, but are secondary to processes occurring in the underlying lymph nodes. Again, though enteric fever is an acute infection, the polynuclear leucocyte takes no part in the inflammatory reaction, indeed, typhoid fever is one of the acute diseases in which there is a leucopenia.

Syphilis

Of tuberculosis and syphilis very little need be said. Syphilis is so protean in its manifestations that it would seem to defy analysis, and, indeed, it is one of the most difficult of the infections to interpret histologically It presents, however, certain remarkable features which are quite outstanding The primary lesion is characterised by an enormous proliferation of the specific organism, with appropriate staining the chancre can be shown to be packed with spirochætes, which are not phagocytosed but lie free in the tissues. At the same time there is remarkably little tissue destruction, and it is, of course, notorious that unless secondary infection supervenes, the primary chancre heals with little scarring Occasionally small foci of necrosis occur, and these are usually infiltrated with polynuclear leucocytes, but for the most part the reaction consists of a dense accumulation of mononuclear cells, lymphocytes, and plasma cells, and a proliferation of the fixed connective tissue elements In the later stages of the disease exactly the reverse occurs Here tissue destruction is prominent, but organisms are very difficult to demonstrate One of the most remarkable features of syphilis is its extreme chronicity It may persist, apparently latent, for years, producing little change except a mild fibrosis of most of the viscera which acquires importance simply because it is progressive It is possible that many of the late manifestations of syphilis are unrecognised as such, but the characteristic fibrosis of the testicle, and the even more characteristic chronic aortitis affecting the ascending aorta, are familiar findings in the post-mortem room.

Tuberculosis.

The macroscopic and microscopic lesions of tuberculosis, or at any rate the more usual types, are so familiar that they need not here be described, but certain points may be stressed The more tuberculosis is studied the more it appears to be a phagocytic disease Once the disease is firmly established in the body diffusible toxins no doubt play a leading part, but I can hardly imagine infection to be possible in the absence of phagocytosis Further, the tubercle bacillus may almost be said to be a disease of a particular system of cells, the mononuclear phagocytes which are now usually grouped together under the name reticulo-endothelial system. It is possible that polynuclear leucocytes may pick up tubercle bacilli as they may pick up any other foreign substance, and I have occasionally seen these cells present in very acute tuberculous lesions, but for the most part the pathogenicity of the tubercle bacillus is closely bound up with the reticulo-endothelial system.

In the more acute destructive lesions the bacilli may be present in such enormous numbers that the tissues seem to serve as a veritable culture medium, but in the more chronic lesions bacilli may be few and far between In fact, there seems to be very often a fairly equal balance between the pathogenicity of the bacillus and the resisting powers of the tissues; a very little will turn the scale either way And this is particularly well seen in the infections of animals which are almost immune Tubercle bacilli introduced into the tissues of an animal such as the mouse are able to establish themselves to a certain extent, but they do this with the least possible inconvenience to the host They are phagocytosed, and they appear to proliferate within the phagocytes, but they seem to exert little or no toxic action, the whole process suggests an almost perfect symbiosis And in the study of tuberculosis in the mouse one cannot fail to be reminded of leprosy in the human being Here occurs the same intense phagocytosis and bacilli are symbiotic within the phagocyte, with, especially considering the numbers of the infecting organisms, the minimum of disturbance to the host (Figs 1 and 2) Leprosy, indeed, can scarcely be distinguished histologically from tuberculosis as seen in the naturally immune animal It is merely an infection by an organism of the great acid-fast group, but one of an extremely low virulence

The Histological Lesion as an Aid in Determining Ætiology

Turning for a moment to another side of the question an interesting feature of the histological aspect of infection is the influence it has on establishing the causal agent of a disease

Acute Rheumatism.

The ætiology of acute rheumatism, one of the most important crippling diseases, is still unknown, though from time to time many organisms have been brought forward as the cause One of the most convincing of these was the rheumacoccus of Poynton and Paine, and at one time I was prepared to accept it partly, perhaps, because I was rather biased in its favour, but chiefly because I was not conversant with the histological lesions of rheumatism It is now generally agreed that the Aschoff node is the essential lesion of acute rheumatism In the myocardium it consists of a small focus situated in the interstitial connective tissue, usually in relation to a small vessel The nodes are multiple and consist in the acute stage of aggregations of large cells of the endothelial type some of which may be multinucleated and mononuclear wandering cells The older lesions tend to shrink down and are eventually represented by minute foci of fibrous tissue These Aschoff nodes are quite unlike any coccal lesion with which we are familiar The difference between the two reactions becomes obvious when, as occasionally happens, they occur simultaneously (Figs 3 and 4) In the case illustrated in Figs 3 and 4 a streptococcal infection was superimposed on an acute rheumatic carditis, and histological examination revealed two distinct types of lesion A mitral cusp showed on one side a typical rheumatic thrombus vegetation with the deeper mononuclear-celled reaction, and on the other an area of ulceration with a polynuclear-celled infiltration and numerous cocci, and a fortunate section through the wall of the left ventricle showed a characteristic Aschoff node lying in actual contact with a small acute metastatic abscess Until an organism can be shown to be capable of causing the Aschoff lesion experimentally, we shall have to continue our search for the organism of acute rheumatism

Forms of Encephalitis

Another instance of the same kind is seen in certain cases of encephalitis The histology of encephalitis lethargica is rather complicated and difficult, but it will generally be agreed that its most constant features are, first, the accumulation of mononuclear cells in the adventitia of the vessels of the affected area, forming the so-called cuff, and secondly, the absence of any glial softening in these areas On these points alone it is possible to make a diagnosis in all but the most unusual cases In the last few years a good deal of attention has been devoted to a form of encephalitis following, or at any rate associated with, vaccination The number of cases of post-vaccinal encephalitis is exceedingly small in comparison with the total number of vaccinations, nevertheless we cannot afford to neglect them It has been suggested that they are really cases of latent encephalitis lethargica which have been lightened up by the vaccination, but the lesions, though not unlike those of encephalitis lethargica, differ in these respects, at least in the only two cases I have seen There is no perivascular cuffing and there is considerable glial softening That the lesions are sufficiently distinct to suggest a distinct disease is the opinion of such experienced and cautious observers as Prof H. Turnbull and Prof J. McIntosh One must admit that there exists a strong body of opinion opposed to this view, but many diseases have been accepted as entities on much less evidence than we have in the peculiar histological appearances of post-vaccinal encephalitis

RHEUMATISM IN CHILDHOOD.

By F J BENJAMIN, M D Durh , M R C P Lond ,
SENIOR ASSISTANT MEDICAL OFFICER, GROVE PARK HOSPITAL LONDON

In the course of an investigation into the relation between social conditions and acute rheumatism in children, carried out by the writer for the Medical Research Council, certain features were noted incidentally, which whilst having no direct bearing on either the causation or the prevention of the disease, and therefore not embodied in the Report,[1] are thought nevertheless to be of sufficient interest to record here

Whilst engaged on this work under the direction of Dr G F Still at the Hospital for Sick Children, Great Ormond-street, London, the writer examined, together with their entire families, 121 cases who were under treatment for rheumatism or had been some time previously, in the selection of these cases only those were taken with quite definite manifestations, nothing apart from chorea, rheumatic carditis, and rheumatic fever, acute or subacute, being accepted All except two of the patients and 35 out of the 242 parents and 318 siblings were actually examined.

A social investigation of these families carried out by Miss Little grouped them into three classes, which were roughly as follows —

Class A —Families having a certain margin over bare necessities, the fathers earning generally up to £4 a week or more

Class B —Fathers belonging mainly to semi-skilled and the more stable unskilled workers earning £2 5s to £3 10s per week but having no margin for anything beyond the bare necessities of life

Class C —Families with means generally below subsistence level and, generally speaking, of the lowest social grade.

Under this grouping the families were found to be distributed as follows —

Class A	16 families
„ B .	77 „
„ C	28 „

A very similar distribution was found in the much larger series of cases investigated at the same time by workers at St Thomas's Hospital, and it is concluded in the report that " contrary to expectation, a comparatively small proportion of rheumatic cases came from families belonging to the lowest and poorest classes " This statement is above contradiction, but does it follow therefore, as is assumed, that the " poorest class of hospital patient shows a lower incidence of rheumatism than the other two " ? In a series of 100 control families from St Thomas's Hospital the distribution was much the same into the three classes, and it would seem simply that there are fewer families amongst our London population to be grouped under " C " than under " B " Would we not get very different figures if, instead of starting with a certain number of rheumatic patients and classifying their families into social groups, we took an equal number of families from each group and then ascertained the incidence of rheumatism amongst them ?

Incidence of the Disease in Relation to Poverty

A certain amount of light might be expected here on considering the percentage of contacts found to be affected with rheumatism in the three social classes in the families of the rheumatic patients investigated ; and in this connexion the St Thomas's workers found amongst the brothers and sisters over 2 years of age of their rheumatic patients 16 per cent in class A, 12 per cent in class B, and only 10 per cent in class C ; very different figures, however, were arrived at from the writer's series as is shown in the following table

This would seem to indicate that the incidence increases pari passu with poverty That better social conditions would go a long way towards eliminating the rheumatic child is shown by the examination of nearly 2000 inmates of Poor law residential schools carried out by the writer for the Medical Research Council, when only 1 per cent of the children were found to be rheumatic This is a very low figure compared with the incidence found in the elementary schools of the education authority, which is stated variously as 2 4,[2] 4 8,[3] and 5 2,[1] and is even more striking when one considers that several of these children going to form the 1 per cent. had undoubtedly been affected with rheumatism prior to entering the schools Rheumatism occurring de novo in these institutions is an absolute rarity as was seen by a perusal of the sickness records At Sidcup homes only two cases of chorea and five cases of acute rheumatism occurred in 22½ years during which time 4198 children had passed through. The schools at Anerley have only had three or four cases of rheumatic fever in 17 years out of about 4000 children, whilst 12 cases of chorea have been noted there in the last 12 years out of 2361 inmates The medical officer of the Ongar homes gave the writer similar remarkably low figures, he could only recall three cases of chorea since 1908, when the homes were first opened, during which time he had seen 2000 children, and he could not recall a single case of acute rheumatism developing without a previous history of similar trouble prior to admission

Incidence of Rheumatism amongst the Exposed Persons (Parents and Living Brothers and Sisters Aged 4 Years and Over)

Class	Number of exposed persons	Cases of rheumatism	Percentage affected
A	83	5	6 0
B	330	30	9 0
C	109	13	11 9

It is the writer's experience that the severity and general prognosis of the disease is influenced adversely by the degree of poverty, and some of the following facts concerning the original 121 patients are written partly in an attempt to bear out this contention.

Sex.—There were 75 females and 46 males

Age at Onset.—The average age of the patient at the onset of the disease was difficult to ascertain with anything like accuracy, and was much the same in each of the three social classes, yet the figures denote a slightly earlier onset in the poorer, less cared-for children, thus —

Class	Number of patients	Average age at onset
A	16	8 2 years
B	77	7 5 ,,
C	28	7 2 ,,

The average age of the children at the time of investigation was 10 9 years

Joints—Just over half the total number of cases had at some time definite joint pains, whilst in 29 per cent of the total this was associated with swelling and pyrexia

Carditis—In 81 cases (67 per cent) the heart became definitely involved at some period of the illness, mitral endocarditis was the most commonly found lesion, being present in 68 instances, combined aortic and mitral disease was noted on four occasions, whilst pure aortic disease was met with once only In eight cases it was thought that myocarditis was present without any valvular defect Extensive pericarditis was present in five instances, of these one was first diagnosed at the time of the investigation, the other four presented themselves at an average of three years from the date of onset of gross involvement of the pericardium, and three were apparently quite fit without complaints and with hearts reacting well to exercise Three of these five cases of pericarditis were from "C" families, though as stated above there were only 28 families in this class altogether

Throat Conditions—These have been very completely dealt with in the report, and the cautious comment that "complete removal of the tonsils does not appear to afford absolute protection from attack by rheumatism" would appear to be fully justified It was not very uncommon to find perfect enucleation of the tonsils had been carried out some considerable time before the onset of symptoms, and it was also interesting to note that removal of tonsils by no means stopped the rheumatic process developing once it had laid its grip on the child, and the writer has seen hearts becoming much worse and even involved de novo following the operation of tonsillectomy

Chorea—At least one attack of chorea had occurred in 82 children (68 per cent) One case had as many as seven distinct and separate attacks Taking into consideration the fact that it was not possible to ascertain definitely the number of recurrences—as some patients were "always having them" or were "never free"—the average number of attacks per patient was found to be almost two, so that a child once having had chorea is fortunate if he or she does not get it again. It is interesting to compare the prognosis of children with chorea falling into class C families (bad) with those in class A (good), for whereas those coming from good families only occasionally had a second attack it was almost the rule for those from the poorest surroundings to have a recurrence and many of these were the children who were "always having it" There were 69 instances in which chorea was the chief, or indeed the only, symptom first noticed and 28 (40 per cent) of these had developed, either at that time or subsequently, permanent heart complications Of 30 cases of chorea which started without the slightest suspicion of cardiac involvement, 5 (17 per cent) by the time of the investigation had developed this complication, and of 21 cases which started their choreic manifestations together with equivocal signs of heart disease—a slight enlargement perhaps or an occasional systolic bruit—such as often gives rise to considerable speculation as to the future welfare of the patient, 5 of these, nearly 25 per cent, had already developed a definite and permanent endocarditis, whilst in two others there was considerable doubt as to the integrity of the heart There was some indication that in this respect also children in the good (A and B) families fared better than their less fortunate brothers and sisters.

It was noted that whereas the combination of heart disease with rheumatic fever was frequent, it was distinctly uncommon to get chorea either during or following an attack of acute rheumatism without first getting cardiac involvement

Subcutaneous Nodules—During the course of the disease subcutaneous nodules were present in 19 cases (15 7 per cent); of the 19 children 17 were seen at a period averaging two and a quarter years after the first appearance of the nodules, and four of these were small under-developed children with big hearts and would probably not reach adult life, but the remaining 13 presented themselves looking fit and well with quiescent hearts and appeared as if they would grow up into fairly useful citizens.

Conclusions

(1) Rheumatism is a disease of poor people and the incidence of the disease may well be in direct relation to the degree of poverty. (2) Rheumatism is very rare amongst children of the poor classes when they are placed in the splendid environment of Poor-law homes (3) Once attacked, the poorer the child the worse the outlook (4) The prognosis of cases with pericarditis and subcutaneous nodules is not so bad as is generally supposed. (5) Whilst unable to point with anything like certainty to any one factor of poverty associated with rheumatism, and whilst being as yet entirely in the dark as to its real ætiology, it can be emphasised here in the words of Dr. Still that it is "by raising the standard of environment and improving the home conditions so that they approximate the well-ordered conditions found in such institutions as those in which rheumatism was found much less common—that we may hope to reduce the frequency of rheumatism in children"

ORGANISATION AND THE RHEUMATIC CHILD

By MARGARET F LOWENFELD, M R C S Eng ,

LATE MUIRHEAD AND MEDICAL RESEARCH COUNCIL SCHOLAR FOR WORK ON RHEUMATISM IN CHILDHOOD

RHEUMATISM in childhood has been known since the early nineteenth century, but it is only within recent years that the numerical extent of the disease has been ascertained and its significance appreciated The position which now confronts us can be summarised as follows From the statistics of 1926, 500,000 of the school-children of the country are estimated to suffer from rheumatism, 10,000 of the children of school age in London are known to be rheumatic, and the vital statistics of 1924 showed that the deaths from heart disease exceeded those from either tuberculosis or cancer

This incidence of disease in the community has two consequences The first are the recurring periods of ill-health and loss of education to the child This is a feature difficult to realise and it is something of a shock to read in a recent report[1] that a quarter of the chronic ill-health of school-children of the country is estimated to be due to rheumatism The second effect is the adult carditis resulting from the disease The extent of this is indicated by the estimation that 60 per cent of rheumatic children ultimately develop heart disease These facts represent one of the many baffling problems confronting medicine to-day It is a problem, however, which is fortunately attracting considerable attention, and the past year has seen the publication of two authoritative reports concerning it and one containing suggestions with regard to its prevention It is the purpose of this paper to attempt to summarise the present position as regards our knowledge of the disease, and to examine the grounds upon which hope of control and of understanding may fairly be based

Three Main Facts

If the disease be considered as a whole, three main facts become evident The first is a marked lack of definition in the clinical outline Only a short time ago, acute and subacute rheumatic fever, chorea, tonsillitis, and carditis were held to cover the manifestations of rheumatism in childhood As these are well-defined conditions, the features of the disease appeared to be clear and easily recognisable But, within recent years, it has been argued that many forms of debility, anæmia, vague muscular pains, dyspepsias, and general irritability should also be considered as of rheumatic origin Furthermore, there is a good deal of evidence which goes to show that carditis can result equally from these as from the more definite forms of the disease, although this is a point upon which unequivocal proof is still needed

The second fact is that the greater significance of rheumatism in childhood does not lie in the typical manifestations to which the name is given, and from which the child can be seen to be suffering, but in a single feature of these—i e , heart disease This, in any but its later stages, is not to be detected by the general public Yet, as is the case with all diseases of children, it is on parents as part of the public that we must rely for the making of the contact between patient and physician The peculiar situation, therefore, arises that the significance of the disease is in a region inaccessible to the observation of patient or mother, and without relation to the severity of the symptoms appreciable by either.

Thirdly, we have no certain knowledge of the actual cause and nature of the disease Two views are current By the early observers, rheumatism, or more strictly, those manifestations of it that had so far been identified, was looked upon as evidence of a particular constitution of the body. Somewhat later, a specific infection seemed the more probable explanation It is on this hypothesis, put forward and developed by F J Poynton and A Paine,[2] that nearly all modern conceptions have been based.

Infection or Diathesis?

To the practical aspect of the question the choice of hypothesis is crucial If it be granted that a given disease be the result, or the result mainly, of a specific micro-organism, then effective measures against the disease must wait upon the successful isolation of the organism, or the practical application of immunological processes yet to be discovered In the period before this has occurred the lines of work most likely to be fruitful will be those directed towards the modification of conditions within and around the child that favour infection with this organism If, on the other hand, the diathesis theory be assumed, other lines of approach to the problem come into view In the disease under review during the past two years certain evidence has been adduced to suggest the value once more of considering the constitutional or diathesis[3] hypothesis According to this view, the outbreak of the disease would depend rather upon constitutional modifications of the bodily habit than an " infection " with a specific organism

The importance of this point cannot be exaggerated If the constitutional view be conceded, the emphasis of study, and ultimately of treatment, is thereby shifted The dependence of treatment upon identification of the organism becomes greatly diminished, and the inquiry shifts to points concerning the endocrine and biochemical make-up of the individual For the designing of work either with regard to the study of the disease or to the devising of means for its control, the choice of hypothesis is of fundamental importance.

Bearing on the Study of the Disease.

Hitherto, all inquiry into the nature of the disease has been conducted by separate investigations specifically designed and carried out alongside of the ordinary clinical work That is to say, while nearly all workers in this field have been keenly interested in the problems of the disease, and have contributed much of great value to our knowledge of its clinical course and manifestations, when a specific aspect has come to be investigated, a separate effort has been needed to examine and report on the material available Two examples of this kind have recently been provided by the reports of the B M A and M R C Committees Just so long as the infective theory of the disease exclusively dominates our conception of it this system is inevitable Bacteriological and statistical work have no bearing upon the treatment of the individual patient at the time concerned until their goal has been reached

If, however, the alternative hypothesis be taken for examination, a different type of attack is possible. Here the nature of the disease is conceived as within the constitution of the patient himself, as has been brought out recently by Hurst[4] According to this view, the whole individual is the subject of inquiry and this inquiry can only be carried out by observation of the individual, whereas by an infection theory the subject of inquiry has to be isolated from material supplied by the patient It is therefore necessary, if this hypothesis be held, to devise methods of study which shall concern themselves with the life-history of the patient, his biochemical and endocrine processes, his response to specific rheumatic infections, and to circumstances of his daily life Considered from this point of view, no attempt has yet been made to carry out exhaustive research, although, as will be seen later, some tentative beginnings are already in being The obstacle to all work of this kind is the nature of the contact at present existing between child and physician It has been abundantly proved that acute rheumatism shows its main prevalence among children of the hospital classes. The contact of the profession with these children is through the work of the general practitioner and the hospital out-patient and in-patient departments. All these are heavily burdened with work, so that, on the one hand, it is only the child who is really ill—that is to say, who is suffering an exacerbation of his condition—who is brought for treatment. On the other hand, it is only possible by the undertaking of special and arduous work to correlate the records of these children. There is, therefore, in the system at present in force no facility for the continuous study of children from the constitutional point of view, and if this is to be undertaken some other machinery must be devised.

Bearing on Prevention and Control

It is in a sense true in this, as in all diseases, that the problem of prevention and control is dependent upon the discovery of the cause or causes of the disease. But it is perhaps worth remembering, in the face of the difficulty of the problem, that the elimination of a disease can be achieved without an exact knowledge of its causation, as in the case of leprosy and typhus in Europe, and that the discovery of the Klebs-Loffler bacillus has not been followed by the disappearance of diphtheria.

In rheumatism it is clear that there are two aspects to the problem, each of which requires separate consideration. The one, that to which attention is increasingly being directed is the care of the heart of the already rheumatic child. The other is the attempt to control the incidence of the disease itself, and to achieve means for the prevention of its appearance in children who can be expected to become rheumatic. These problems, though intimately related, and common in origin, need to be kept very carefully distinct. All chances of success depend upon their separate consideration, and it is the failure to do so that determines the ineffectiveness of so many of the proposals at present current.

It is obvious that any scheme, either for the care of children already rheumatic, or for the study of the disease, must be based upon a definite hypothesis of the nature of the disease. Up to 1922, as has already been pointed out, work upon rheumatism has been conceived from the infective point of view and the results have been, on the whole, disappointing. In America a new step was taken with the formation of the Association for the Relief and Prevention of Heart Disease. This was intended primarily for adults, and embraced all forms of heart disease, but in 1915, W St Lawrence[5] adapted these methods to the study of the effect of rheumatism in childhood, and the first children's cardiac clinic was opened at St Luke's Hospital, New York. The aim of this clinic was the continuous treatment and observation, upon a classified system, of rheumatic children, with special reference to their heart condition.

In this country nothing of the kind was attempted until 1923. In this year, interested by St Lawrence's work, Prof Leonard Findlay and the present writer organised a clinic at the Royal Hospital for Sick Children, Glasgow, for the continuous supervision of rheumatic children attending that hospital.[6] As a result of this work certain facts became clear. It appeared that the manifestations of rheumatism in childhood, usually covered by such terms as the acute and convalescent stages, needed the addition of a third term for a complete description—that of the quiescent stage. Under this head is considered the period between attacks, when the disease smoulders, but is not apparent. Upon the conception of this quiescent stage the whole work of a supervisory clinic is based.

A New Basis of Classification

The second point of note arising out of the clinic is that of the importance of the basis of classification of these children. Hitherto, all classification of rheumatic children, whether explicit in records, or implicit in the mind of the observer has been based upon the *clinical form of the disease*—e g, rheumatic fever, chorea, tonsillitis. It has, however, been agreed that the significance of the disease does not lie here, but in its tendency to cardiac involvement. These terms, therefore, offer no help to the observer in his attempt to protect the future of the child. The use of them, moreover, necessitates a somewhat lengthy and detailed note on the cardiac condition being added to each case, and renders very difficult any survey of a number of cases.

For the working of this clinic the emphasis was shifted, and a classification was devised upon the basis of the children's cardiac history. Since the clinical findings by different observers in any given cardiac case are not always necessarily identical, an endeavour was made to arrange the classes so the discrepancies arising from this source should be reduced to a minimum. The classification finally adopted was as follows:—

Class P	Potential heart cases—that is, cases with definite rheumatic history who have never had cardiac involvement, and are now well
„ A	Cases with a history of definite rheumatism with cardiac involvement, which has now disappeared
„ B	*Cases with a definite rheumatic* history and present signs of cardiac involvement, but no symptoms referable to the heart
„ C	Children with a definite rheumatic history and present signs and symptoms of cardiac involvement, but no disability for ordinary life
„ *D 1*	Cases with a definite rheumatic history, present signs and symptoms of cardiac involvement, and definite disability for ordinary life
„ D 2	Cases without a rheumatic history, but showing signs of a cardiac lesion, and with some definite disability for ordinary life
Miscellaneous	Cardiac irregularities, effort syndrome and cutaneous eruptions supposed to be of rheumatic origin

From a practical point of view such a classification has the following advantages. When the original classification has been made, subsequent notes are reduced to a minimum. "Mild Class B," for instance, can describe all the essential points about a case. Whether this lesion is the result of an acute rheumatic fever, of growing pains, or of tonsillitis, though of interest, from the point of view of immediate treatment prognosis or recommendations to the mother, is of comparatively little significance. It also makes possible a rapid survey of a large number of cases without elaborate cross-indexing. By collection of those children whose classes have been changed during the year, immediate information is given regarding percentage improvement or deterioration in cardiac condition of the children. Further, any class of child can be quickly and easily isolated for reference, examination, or experimental therapeutics.

It will be noted that this classification embraces only children already the subject of a *definite* rheumatic condition. This was deliberate, because the original clinic was devised to study the possibilities of prevention and control of heart disease in children who were already rheumatic. In other words, to keep Class P children from moving into any other class, and to move as many of those in the other categories as possible to Class A.

An Attack Upon the Rheumatic Constitution

Another fact stands out clearly as the result of the work of this clinic—viz, that while work of this kind is very useful and effective *within its own limits*, if an attempt is to be made to achieve the *prevention* of rheumatism, a still earlier attack must be made upon the disease. But since all signs of rheumatism in children, other than those of acute rheumatic fever, chorea, and tonsillitis are ill-defined and susceptible of varying interpretation, the formation of a clinic upon this basis will involve the assumption of the existence of a rheumatic constitution. That is to say, children of rheumatic stock and those children who are subject to all forms of vague and indefinite rheumatism will also need to be included Not only must the basis of the clinic be thus widened, but the treatment of these children must follow different lines, and be directed as much towards raising the child's general resistance, as to combating his definitely rheumatic tendencies

[5] Hospital Service Series, May, 1920, pp 151–181

[6] Brit Med Jour, 1926, i, 817 and 820

These are as yet hypothetical conceptions and need wide testing before their acceptance One attempt to do so is already in existence in the form of a "children's cardiac clinic" at the St Marylebone General Dispensary, which has been in operation since 1926 At this clinic children, whether definitely or possibly rheumatic, are received from the age of 2 years, and supervised until puberty, when they join one of the adult clinics of the dispensary The modifications introduced into the classification are as follows —

1 Class P. becomes subdivided into—

P 1	Children with history and complaints suggestive of rheumatism, no cardiac involvement, and *no* disability for ordinary life
P 2	Children with history and complaints suggestive of rheumatism, no cardiac involvement, and *some* disability for ordinary life
P 3	As in original classification

2 Class B becomes subdivided into—

B 1	*As in original classification*
B 2	Children with a history suggestive of rheumatism, present signs of cardiac involvement, but no symptoms referable to the heart

The standardisation of the classification with that already in use elsewhere allows both accurate comparison of results, and full development of preventive measures in either

Since the publication of the report of the Glasgow Clinic, the Science Committee of the British Medical Association have sat for a further consideration of the problem, and have issued a second report[7] on the Prevention and Control of Juvenile Rheumatic Infection In this communication the existence of the quiescent stage is accepted, and the principle of continuous medical supervision emphatically recommended The details of the one centre to which reference is made in the report are, however, so unsubstantial that it is impossible to discover upon what lines it is organised, what class of child is accepted, and how classified, and upon what lines the suggestions of treatment are made. The actual proposals of the report also suffer from the same vagueness; and this is unfortunate, because in the medical supervision of rheumatic children we have not only a method of treatment but also an instrument which can be used both for the examination of the effects of treatment and to the study of the disease itself At present treatment of the disease and inquiry into its nature are far too apt to be kept in watertight compartments What is needed is a method by which the natural history of the disease, the factors influencing or retarding its development, the effect of attempts to modify the constitutional habit, can be provided in a large number of cases in such a form as to be readily and easily manipulated and studied It should be possible to achieve this and simultaneously to provide abundant material for ætiological and therapeutic research

It is clear that work of this kind opens new avenues for correlated research, while it demands some modification in our attitude to systems for control of disease Such methods, by providing material for investigation upon any desired lines, and by demonstrating the life-history of the disease, will exactly fill the obvious gap in our present system. It is true that there may be difficulties in associating these principles with the work of a voluntary hospital, but they are, I am confident, not insuperable On the other hand, by work of this kind a weapon can be forged for the study of the constitutional hypothesis of rheumatism, which, it is contended, is the next and most hopeful step to be taken towards an understanding of the disease

SENESCENCE AND SENILITY.*

BY LEONARD WILLIAMS, M D Glasg,

PHYSICIAN TO THE LEGAL AND GENERAL ASSURANCE SOCIETY

[Dr Leonard Williams commenced by acknowledging the wit and wisdom of previous contributors to the subject, and pleading that as senescence "like love is a story which never grows old, something may be gained if every now and again an effort be made to reconsider it in the light of modern fashions in medical thought" Pointing out that the circulatory system contains the physiological secrets of nature, he deprecated the preponderant rôle assigned by clinicians to the corpuscles, and urged due appreciation of the functions of the plasma as essential to the understanding of physiological and clinical phenomena, more especially where neurological problems are concerned "The impetus of our start in life," he said, "the momentum which is to keep us in being are derived from the liquor sanguinis which we inherit from our forebears", and the interesting question in reference to the subject of the discourse was what ingredients in the plasma determine long life to some, and to others premature death, because the momentum is at an end He continued —]

THE POTENCY OF THE PLASMA

The mere enumeration of the ingredients of the plasma suffices to impress us with its capacity for variation, and causes us to wonder that in any given individual its composition should remain as uniform and constant as, judging by the consistency of character and conformation, it certainly does The primary pattern, the broad lines of its composition, are evidently determined at birth They are profoundly altered at puberty, it is true, and as the years roll on, the detail becomes modified; by study and suffering, refined, by selfishness and materialism, brutalised, but the general make-up, both physical and mental is retained with surprising uniformity to the very end

This potent fluid we know to contain first and foremost foodstuffs, among which we must include vitamins These are for the nourishment of the tissues, to repair waste, to supply fuel, to liberate energy We also know that before the foodstuffs, as originally ingested, can reach the blood stream, they are warmed, churned, and liquefied; and then, for the most part, they are subjected to a complicated chemical process in the liver Some of them, nevertheless, escape the cleansing fires of this formidable viscus, and succeed in gaining direct access to the blood through the thoracic duct I shall return to this matter later, but I may be allowed to pause here, to emphasise the obvious, by pointing out that if these simple facts of elementary physiology were simply faced and squarely acted upon, there would be far less premature senescence in the world than there is now If the pristine adolescent purity of the plasma were preserved throughout the adult period, both senescence and senility would be indefinitely postponed The impurities which creep into the liquor sanguinis, and guide us gradually to our destruction, are derived from the material which we ingest If all of it could be passed through the hepatic furnace, matters might be better than they are It is the backstair of the thoracic duct which causes most of the trouble In this connexion, let us not forget the fact of which Sir Humphry Rolleston[1] recently reminded us—namely, that Carrel, Chamby, and Grandcourt have conclusively shown "that with frequent washings to remove waste products, tissue-cells can be cultivated indefinitely for years in vitro, and have an unlimited capacity for multiplication" But must we blind ourselves to the fact that "it's the washings as does it"?

---

* Being the Cavendish Lecture (abridged) delivered before the West London Medico Chirurgical Society on May 27th

[1] Concerning Old Age, Trans Roy Institut, May 13th, 1927

But the plasma does not restrict its recruiting activities to the gastro-intestinal tract; it lays other systems under contribution. The most important of these is the endocrine system. I need not insist upon the importance of the subtle essences of the glands which compose this system. The fact that they are poured straight into the circulating fluid without the intervention of a duct, of itself suggests their transcendence, as though Nature, in her thrift, dared not risk the loss or waste or change of one drop of so subtle and precious an elixir. We have only to recall what the absence of the thyroid tribute spells in cretinism and myxœdema, what the suprarenal, in Addison's disease, the meaning of the absent gonad at puberty, and of the lazy pituitary in adolescence, to realise the profound influence which these glandular subsidies to the plasma exercise over the maintenance and efficiency of the individual, for at any given moment a man may be said to be the resultant of his hormones. Of the ferments, catalysts and antibodies which are obviously contained in the liquor sanguinis we know next to nothing. But we know them to be there, not only adding to the complexity of the fluid, but enhancing and reinforcing its preservative and protective value to the economy.

[The lecturer then proceeded to point out that the functions of the plasma, though primarily donative, are more emphatically and essentially depurative, so that if a man persistently presented his plasma with unsuitable material, the extra energy that would be called for would lead to earlier exhaustion of the whole machine, the hostile material finding its way into the liquor sanguinis by means of the thoracic duct. Much of the premature senescence thus induced the lecturer attributed to gluttony and cookery, a pusillanimous acceptance of things as they are having been engendered. He continued :—]

COOKERY AS PRACTISED

In saying this, I must not be understood to condemn cookery as such, but merely the crude and cursory cookery of the day. Cookery is an art, which, properly practised, as an art, by artists, materially adds to the æsthetic enjoyment of the few good things of life, but, as usually practised in this country, cookery is merely a bad habit. Performed as it is, automatically and perfunctorily, it makes nourishment nasty and unappetising, and, by depriving food of vitamins and other subtleties, and in other ways, renders it foreign to our digestive juices. Cookery, as at present practised, is nothing but a species of more than usually stupid snobbery. Like the grand piano which, while suitable in the palace, becomes a piece of fantastic foolery in the cottage, cookery is too often merely penury masquerading as magnificence. Most sensible people would rather drink water than bad wine, but, judging by the common custom, the same people would rather eat badly-cooked food than eat uncooked salads, dairy produce, and those kindly fruits of the earth for which they vociferously thank the Lord on Sunday, and relegate to an emasculating stewing-pan on Monday. And this senseless habit not only imposes upon us, and upon our children, a series of dire deficiency diseases, of which ugliness is one, but it also confers on us most of the microbic maladies which decimate us. Our food is subjected to boiling, baking, braising, stewing, grilling, and other firing processes, and is thus made into a culture-medium for microbes. It is manipulated by the chapped and septic hands of a frowsy and uneducated frump—for the most part fat—to whom we are foolish enough to entrust the work proper to a skilful artist. And we tamely eat the resulting concoction in the pious belief that it keeps up our strength, and are surprised that our jaded liquor sanguinis insists upon deteriorating. *Homo sapiens* may be wise and watchful in some matters and clever and cunning in others, in the matter of his food, he is nothing more than an ignorant and obstinate simpleton.

An impure plasmic environment, serious as it must be in the case of all the cells in the body, will disturb the various systems in the order of their complexity or nobility of organisation; the nervous system first, then the glandular, and so on through the muscles downward to simple connective tissue. For the earliest signs of degeneration, then, we must interrogate the nervous system, more especially that part of it which is concerned with control and intellectuality. These are typically the first to show signs of decay, the flower goes before the leaf, the leaf before the twig, but that is not invariably the case. In one disease, at any rate, Parkinson's disease, which may be described as the personification of old age—" where palsy shakes a few sad last grey hairs "—the various systems seem to be smitten almost equally and simultaneously. I have said that premature senescence renders us tamely submissive to evils as we encounter them. Man is by nature a hunter and a fighter, and when he ceases to be so, he has already begun to degenerate. When youth loses its fire, maturity its illusions, and middle age its ambitions, it is surely a sign that the brain cells are being bathed by a liquor sanguinis which is already bereft of its pristine vigour, and the earlier in life the backsliding occurs, the more certainly does it point to an active intoxication of the plasma, to a filling up of the cup with cumulative culture bouillons. The genus homo inherits from his simian ancestors a certain playful devilry of spirit, indicated in youth by a sense of boisterous humour. When that gives place to a square-toed pomposity of attitude, as who should say of all things, " we are not amused," then it means that the plasma has been deprived of its erstwhile purity and the descent has begun. That every time of life has its appropriate attributes I am willing enough to admit. The airs and graces of youth sit badly enough on the aged. Tully said of Hortensius, " He remained the same, but the same no longer became him." This particular affectation is less prevalent among men than it is among women, but it is ugly in either sex because it is essentially forced and unnatural. It is not the external gestures of youth that the senescent should seek to retain, but the spirit of adventure and the chase, and these can be displayed in the mental arena no less than in the muscular. Smug-faced satisfaction is the one great and unforgivable sin.

THE VIRTUES OF FASTING.

[The lecturer then urged that to maintain the sovereignty of restraint and moderation over insidious and insistent invitations to indulgence demanded watchfulness and determination. In brief, this meant a certain measure of fasting, and he used the word advisedly, indicating that fasting and starving are not synonymous, for when a man fasts he lives on his redundant reserves. He continued :—]

It is a strange and saddening reflection upon our therapeutic methods that our attitude towards the *vis medicatrix naturæ* should be so shamefaced and stealthy. We recognise in our heart of hearts that all our healing is due to the wizardry of its working, and yet we treat it as though it were an unqualified assistant, open association with whom would surely get us into trouble with the General Medical Council. We muddle it with mixtures, and vex it with vaccines, we slice it with scalpels and fix it with forceps, but we are seldom firm enough to give it a free hand. And it is more especially in the matter of feeding that the free hand is withheld. At a time when the energies of the whole economy are bent upon restoring the equipoise by attacking a microbe, neutralising a toxin, or righting a metabolic wrong, it is forced to turn aside in order to deal with uninvited and unwelcome foreign guests which, in the form of beef-tea and other so-called nutritious, but in reality excrementitious, concoctions, are poured into a stomach which is screaming aloud for repose. In such circumstances the only food which even spare people require is there, in *their tissues*. Moreover it is there, in a physiologically assimilable form, prepared in Nature's kitchen and stored in her larder for use in such a crisis as we are considering. But, instead of allowing the economy to utilise this partly digested food which is willing and waiting. we compel the wasteful expenditure of precious energy by constraining the victim to undertake the onerous and laborious task of digesting and assimilating alien and unwanted material In comparison with the ordinary British invalid, the forcibly-fed Strasbourg goose is an ascetic

If this aspect of the matter is explained to them there is as a rule. very little difficulty in inducing people to face the ordeal of fasting . more especially in chronic metabolic diseases. in which the patient though never very ill. is never quite well and is properly impatient of his impaired capacities The only trouble arises from the fact that so many people especially women, are deeply imbued with the epic and esoteric element in all illness. We. of the profession. are charged to do something , preferably something mysterious or heroic An operation, an X ray examination. a cystoscopy, a sigmoidoscopy—certainly · but a policy of ' wait and see " what Nature can do for herself without the meddlesome hand of man—never

And yet fasting is the simplest and safest of all remedial measures It is Nature s way. During the first few days when the expectant stomach, accustomed to stimulation is made to suffer the sorrows of deferred hope. it may be difficult to discern any blue in the sky. Nevertheless, by arousing the fighting instinct latent in most people. even the gloom of these few days may be lightened by the sure prospect of ultimate victory ; and with these days behind him the patient is impelled to wonder why he ever eats anything

ARTIFICIAL REJUVENATION

[Referring to the popularity as a topic of tea-table conversation of procedures for artificial rejuvenation, Dr. Williams gave it as his opinion that Voronoff s reasoning was sound, adding that he himself had seen excellent results from grafting operations He would however like to add :—]

In my judgment the Voronoff operation does not prolong life but it does prolong efficiency for the duration of life. It contributes nothing to longevity but a great deal to the prevention of morbid senility It possesses the inestimable merit of enabling a man to make his exit by crisis instead of by lysis My point, however. is that the operation ought never to be necessary. Under the present dietetic dispensation there will always be hundreds of people whom it will benefit enormously ; but if such people had only paid a due respect to the purity of their liquor sanguinis, the necessity for grafting would never have arisen The best measure of rejuvenation is a thoroughly depurated blood-supply and the best means for securing that is to practise moderation punctuated by fasting. It is better to find salvation in a dietetically sober and righteous life than to seek to conjure back competence by a cutting operation. Nor must it be supposed that the discipline of fasting as a measure of preservation is an idle fancy altogether lacking in scientific sanction. In a recent lecture Sir Humphry Rolleston [2] says —

> ' It is interesting to recall that in the humble planarian flat-worms the life cycle may be dramatically changed · by starvation they not only become smaller but their structure becomes simpler By alternate starving and feeding these flat-worms have been kept stationary while others passed through nineteen generations thus showing that the duration of existence of cells is not so much a matter of time as of the work or metabolic changes that go on inside them '

And yet though by laborious days, occasional fasts and grafts. and otherwise we may succeed in preserving our plasma in a state of cleanliness thus preventing precocious decadence the ugly fact remains that sooner or later. in one form or another, senility awaits us all For. although by wisdom the plasma may escape pollution, it cannot in the nature of things avoid eventual dilution And we all desire that the stage of dodderance may be short Though we are taught to pray to be delivered from sudden death in the case of those we love—a selfish prayer—each one is entitled to hope for a sudden termination in his own case The stage of the slippered pantaloon has no attraction for any of us Rather do we envy the fate of Oliver Wendell Holmes's one-horse shay which went for a hundred years and a day. and then disappeared into nothingness :—

> " All at once and nothing first
> Just as bubbles do when they burst "

That is a natural and even laudable ambition. but it were unreasonable to expect escape from some evidences of gradual decline This is a matter which would seem to depend very largely upon the endocrines

[The lecturer then alluded to the natural sequence in which living dissolution occurs saying that the higher centres as a rule mercifully succeed in maintaining their dominance till the end He quoted Bacon and Swift as caustically critical of the defects of old age, and closed by presenting another side of the picture in these words —]

There are certain qualities of head and heart derived from the manifold experiences of service, sacrifice, and suffering. inevitable in a long life. which are peculiar to the unpolluted plasma of natural senility, and these qualities at their best. are of immense advantage to those families and communities which are wise enough to profit by them. Among such qualities are judgment insight. tolerance. and equanimity These are natural to the stage of healthy old age, and it is these which we must seek to cultivate when the signals warn us that we are nearing the place ; when we become coldly conscious of the glimmer of twilight ' When lengthening shadows on the lawn. give notice to the startled grass that darkness is about to pass '

Clinical and Laboratory Notes.

A CASE OF

HYPERTROPHIC OSTEO-ARTHRITIS OF THE CERVICAL SPINE

BY A W HENDRY, M.D. ABERD , M.R C P LOND '
ASSISTANT PHYSICIAN, ABERDEEN ROYAL INFIRMARY,
AND
ANDREW FOWLER, M B ABERD , F R C S EDIN ,
ASSISTANT SURGEON TO THE INFIRMARY

FOR several reasons we consider the following case of sufficient interest and importance to be worth record

A. B , a young man aged 21, was sent to the out-patients' department Aberdeen Royal Infirmary, in October, 1926 He complained of weakness and uselessness of the right hand

History —About five years ago he noticed that the right hand was weaker more clumsy in action and more easily tired than the left Two years ago he noted that the right hand was smaller than the left. At no time was there pain or discomfort in the hand apart from a tendency to become easily tired

General Condition and Previous History —He is big. strong and active, a warehouseman and has never been away from work on account of illness. He had measles at the age of 5, complicated by suppurative otitis media. This ear condition became chronic and persists. Apart from a fall when 12 years old there is no history of trauma. This fall apparently did not cause any disablement.

Condition on Examination —All joints of the upper extremities moved fully and freely There was definite weakness and wasting of the muscles of the right arm as follows · the intrinsics of the hand and the flexors and extensors of the wrist and fingers The muscles of the right upper arm were, perhaps, a little smaller and weaker than those of the left side, but there was no definite wasting We thought this little difference of the upper arm muscles due to disuse or rather to the fact that the left arm was used a great deal more than the affected arm. There was no incoördination and no tremors of either upper extremity. Sensation was defective for wool and pin-prick along the ulnar border of the right forearm. Neck movements were slightly restricted in all directions, especially flexion to the right. On the right side of the neck there was noticeable a protuberance just above the middle third of the clavicle. This protuberance felt hard and bony. Trunk movements were full and free. Sensation over the trunk was perfectly normal for wool, pin-prick, and thermal stimuli. The abdominal and cremasteric reflexes were present and equal on the two sides. In the lower extremities movements, power, coördination, and sensation were normal. The knee-jerks were too brisk, and there was a tendency to a brief clonus on the right side. The plantar reflexes were definitely flexor in type.

There was no sphincter trouble. No evidence of cervical sympathetic dysfunction was present. There were no Heberden's nodes. Syphilis may be excluded, the W.R. being negative. There was no evidence of genito-urinary infection. We considered the symptoms due to pressure on the lower roots of the brachial plexus of the right side.

Radiograms show a massive enlargement of the lower cervical spine. On the anteroposterior view (Fig. 1) there are two lateral curves, the upper concave to the right, the lower concave to the left. The lateral view (Fig. 2) shows an increased forward bending about the middle of the cervical spine. The intervertebral discs have apparently disappeared in places. The bodies, laminæ, and spinous processes of the lower cervical vertebræ exhibit a marked increase in density with apparent narrowing of the intervertebral foramina. Those in the lower part of the cervical spine cannot be made out. Radiograms of dorsal and lumbar spines show no osteo-arthritis.

Discussion

This is presumably a case of hypertrophic osteo-arthritis of the cervical spine. The condition is not common. Elliott[1] was unable to find in the literature any specific reference to it. Our case would appear to support his view that the lower cervical region is especially susceptible to this disease. We do not wish to enter here into a discussion of the ætiological factors, but would note the presence of a focus of chronic suppuration—namely, otitis media. We would suggest that the tendency to select the lower cervical spine is not unconnected with the joint mechanisms of this part, for here we find a flexible segment connected to a relatively rigid portion.[2] This would appear to be a likely site for the occurrence of special stresses and strains and therefore likely to determine the site of the osteo-arthritis. The case differs from those cited by Elliott in that pain is not and never has been present. It also shows, as far as radiograms are concerned, a greater hypertrophy of the affected spine.

Lateral view of cervical region

A FURTHER NOTE ON THE WATER-SOLUBLE OVARIAN HORMONE.

BY F. DICKENS, M.A., PH.D.,

E. C. DODDS, M.D., PH.D., M.R.C.P. LOND.,

AND

D. J. TRESCOTT BRINKWORTH, A.I.C., A.C.G.F.C.

(From the Biochemical Department, Middlesex Hospital.)

AFTER reading the paper by E. Laqueur, P. C. Hart, and S. E. de Jongh in THE LANCET of May 28th we feel that some further remarks are necessary in order to clear up certain points raised by these authors. In the first place we should like to draw attention to the fact that our paper was intended merely as a note upon a method evolved by ourselves for obtaining the hormone in a water-soluble form.

Whilst we were familiar with the published work on the subject, including that of Prof. Laqueur and his collaborators, it was clearly impossible to enter into a detailed historical review. Since, however, we are taken to task for not referring to a paper in the Proceedings of the Royal Academy of Sciences,[1] it will be as well to state that we were well acquainted with its contents, and had, in fact, repeated some of the methods given there. We can only repeat our statement, "in our hands, these methods have proved unsatisfactory." One of the difficulties encountered in this work was the great variety of methods given, with little or no indication as to which one the authors finally recommended The methods are almost entirely confined to preparations from liquor folliculi One method is described in which the proteins are precipitated with colloidal ferric hydroxide, but the authors state that this method is not satisfactory A second method consists of extracting liquor folliculi with chloroform Our difficulty arose in the separation of the emulsion formed, and we were unable to obtain any assistance in this direction from the published details The authors state :—

---

[1] Elliott: Journal of Bone and Joint Surgery, January, 1926, vol. viii., No. 1.

[2] Treves and Keith: Surgical Applied Anatomy, 1918, p. 652.

[1] Laqueur, E., Hart, P. C., de Jongh, S. E., and Wijsenbeek, I. A.: Proc. Roy. Acad. Sci., Amsterdam, 1925, xxviii., No. 10.

> "We found it useful to prevent the forming of emulsions when shaking out with the volatile solvent, this may be done by completing the coagulation of the proteins by adding salt or acid, by centrifugalising, &c"

Again they state —

> "Besides chloroform we used carbon sulphide, carbon tetrachloride, benzene, petroleum-ether, tetralin, ligroin, ether, acetone, and ethyl acetate In principle all these yielded identical results, but our experiments are still too few in number Often the residue from the volatile solvent at first formed an emulsion with the water, in most cases, however, a simple filtration made the fluid clear, often the solution was water-clear from the first, and then its content of solids was minimal Probably this depends, besides on the nature of the solvent (which must dissolve menformon with as little water-soluble impurities as possible), on the freshness of the follicular liquid, and further on the completeness of the precipitation of the proteins, which then take the other colloidal constituents with them Finally the completeness with which the volatile solvent is removed plays a part, eventually also the temperature at which this has been done (We worked at atmospheric pressure, in vacuo, and in an air current at about 35°C)
>
> "All these factors, and many more are still to be investigated much more completely"

It can be seen that the authors do not intimate which of the alternatives is really the most successful, and it would appear that we were unfortunate in choosing one of their less successful recommendations

In their recent paper in THE LANCET Laqueur, Hart, and de Jongh give an account of the method which they now employ for the extraction of the hormone from placenta As yet we can make no comment upon this method since we have not had an opportunity of investigating it thoroughly We may mention, however, that it appears to differ considerably from any of those previously published by these authors

With regard to the physical and chemical properties of our extracts, we can only infer that the authors have mis-read our papers, since we have never suggested that our extracts consisted of the pure œstrus-producing hormone; indeed this is clearly not the case This is shown, for instance, by the fact that the further purification of the substance is a comparatively simple matter, and is at present being investigated by us Thus, with regard to the effect on blood pressure the Amsterdam workers state that " . whereas less pure preparations such as have been described in England by Dickens and Dodds towards the end of 1925, exert an appreciable lowering action upon blood pressure We think those authors are not quite justified in ascribing this to the hormone itself, it is more probably an effect of the impurities " In the paper referred to [2] this action was not, of course, attributed to the hormone at all, but was described as a property of the extract prepared by the modification of Herrmann and Fränkel's and Allen and Doisy's method, which we were then employing for preparation of an active substance from ovaries and placenta This is made quite clear in the paper in question, where we have throughout referred to the material as "the extract" and not as "the hormone" The water-soluble material prepared by the process which we recently described is without action on the blood pressure

The position with regard to this hormone is similar to that of insulin The earlier crude extracts caused a marked depressor effect, as was shown by Dudley in 1923 [3] Subsequent purification clearly showed that this depressor action was due to impurity, which, as a result of further investigation, could readily be removed

Similar considerations apply also to Laqueur, Hart, and de Jongh's criticisms of our observations on the chemical and physical properties of our recent extracts We recorded these since the extract was prepared by a new method and its properties were therefore considered of sufficient interest to report. The fact that our material, the purification of which we have reason to believe we will be able to continue much further, contains sulphur and gives certain qualitative reactions, is, of course, no indication that the pure hormone itself is responsible for these properties There is nothing in our paper which could justify such an assumption It is clear however, that our material resembles the final products of Laqueur and his co-workers in that neither is soluble in ether or acetone, and both are soluble in water. This would tend to confirm the view recently put forward by us that our 1925 fatty material, like that of Herrmann and Fränkel and Allen and Doisy, probably consisted of the water-soluble substance retained in solution in fat-solvents by the presence of large quantities of inactive fatty substance.

We have other evidence confirming the ease of adsorption of the active principle Thus, after prolonged hydrolysis of the water-soluble product with dilute acid and subsequent neutralisation, although the solution retained a considerable portion of its activity the addition of picric acid solution did not cause the formation of a precipitate of picrate Thus the method of preparation which we have adopted probably involves the adsorption of the active principle on to the precipitate of protein picrate formed on adding picric acid to the acid digest

We are extending our observations in this direction and these will form the subject of another communication

AN ATYPICAL CASE OF CONGENITAL JAUNDICE WITH HEPATIC CIRRHOSIS

BY R L MACKAY, *M C.*, B SC, M D GLASG.

THE comparative infrequency of fatal jaundice in the early days of life and the fact that a post-mortem examination was performed, justify description of the following case.

Clinical History—On August 22nd, 1924, I was called to see a baby then 11 days old. The mother complained that during the previous seven days the child had become increasingly yellow At birth it had had a normally coloured skin and weighed 8 lb For five days it was breast-fed, but about the fifth day the midwife in attendance noticed a suggestion of jaundice and to arrest this ordered the substitution of a proprietary food for the breast-feeding There had been practically no vomiting till the ninth day, when it was given castor oil

On the eleventh day, when I first saw the child it was weakly and wasting, had widespread jaundice of the skin, lips, and sclerotics, and yawned frequently The facial lines or furrows were very prominent, giving an "old man" appearance Temperature, pulse, and respiration were normal. The umbilicus was not quite healed but was free from any sign of inflammation and there was no rash around the anus or on the buttocks The fæces were yellow-green in colour and slightly curdled, but no mucus was present No abdominal tenderness was detected, but the liver was much enlarged and easily palpable The spleen was not palpable There had been no vomiting in the previous 24 hours Calomel gr ¼ was given

The condition then developed as follows · Twelfth day: Constipated Hyd *c* cret given Sod cit added to feeds. Thirteenth day · Child appeared better Jaundice less deep No yawning No marks on buttocks Breast-feeding resumed Sixteenth day Jaundice still marked Took parents' blood for Wassermann *reaction* Both proved negative Twentieth day. Slight *papular* eruption appeared on buttocks, not much different from the common maculo-popular napkin rash No snuffles, no *coughing, no* vomiting. jaundice slightly less marked Child still on breast, but not gaining ground Twenty-fifth day A small spot of fresh blood observed in the stool No vomiting, no colic, no diarrhœa No rash now on buttocks Twenty-sixth day Slight vomiting of fresh blood occurred In the evening this recurred, and then became frequent, until the child died about 4 A M on the twenty-seventh day, bleeding from nose, mouth, and anus Though a request had been made several times for it, no sample of urine could be obtained

---

[2] Dickens, F, Dodds, E C, and Wright, S Biochem Jour, 1925 xix 853

[3] Dudley, H W Ibid, 1923, xvii 376

Family History —The mother, aged 41, had always been healthy and robust She had a sallow complexion There was no history of jaundice in any of her relatives and no personal venereal history Her Wassermann reaction was negative The record of her pregnancies is as follows (1) Male, alive and well, aged 11 years Sallow colour, Has a slightly dilated heart, a mitral murmur, and occasional albuminuria (2) Male, miscarried at 6½ months (3) Male died aged 10 days, from jaundice (4) Female, died, aged 1½ years, from pneumonia (5) Female, died aged 2¼ years, from whooping-cough and convulsions (6) Female, died from jaundice, aged 3 weeks Premature at 8 months (7) Female, died from jaundice, aged 4 weeks (the present case) (8) Male, born March, 1926 A perfectly healthy child

The father has a sallow complexion, as have also his brothers and sisters None appear to have had jaundice No venereal history obtained Wassermann reaction negative Teetotal Recent erysipelas

Post-mortem Examination —The parents would only permit a short examination of the abdominal cavity This was carried out about ten hours after death by Dr W M Brown and myself The following points were noted —Mouth full of froth and blood Stomach contained large clots of blood, source not ascertainable, mucous membrane bile-stained, no pyloric stenosis Small intestine walls hæmorrhagic, lumen full of blood Large intestine no marked changes in walls, blood in lumen, a few recent adhesions around colon. Anus blood exuding from it, skin normal Peritoneal cavity no free fluid Liver much enlarged and firm in consistence, deeply bile-stained, surface smooth Gall-bladder normal in size, containing a little viscid muco-bile, cystic bile-duct patent. Common bile-duct a small soft mass, size of a pea, covered with mucus but of a consistence firm enough to block the duct was found in the lumen, it was easily broken up by the fingers It was difficult to pass a probe through the duct to the duodenum Spleen normal in size and appearance Umbilicus and vein no sepsis present.

Histological Examination —I am indebted to Dr John S Young, of the Department of Pathology, Glasgow University, for the following report on the sections —Liver advanced generalised pericellular cirrhosis, liver cells much destroyed, bile-ducts *dilated and full* of bile, but the lumen everywhere intact, no spirochætes present Spleen shows nothing abnormal, no spirochætes present (Levaditi's method) Kidneys a slight increase in interstitial tissue Common bile-duct lumen patent and normal, no inflammatory changes in wall

Diagnosis

The clinical course of this case made exact diagnosis difficult during life, and the post-mortem findings, distinctive as they are, tend to increase that difficulty Jaundice occurring in infancy and childhood may be considered as likely to be one of the following varieties —

(1) *Simple icterus neonatorum* is definitely eliminated by the long duration, the enlarged liver, the hepatic cirrhosis, the hæmorrhages, familial history, and fatal ending

(2) *Infective jaundice* (Winckel's and Buhl's varieties) The absence of any signs of sepsis, of umbilical hæmorrhages or of pyrexia, hæmaturia, splenic enlargement, cyanosis, or of a prevailing epidemic, appear to be strong evidence against this variety while the advanced nature of the cirrhosis make it probable that this had begun during intra-uterine life

(3) *Acute catarrhal jaundice* affects older children, is rarely fatal, is unaccompanied by widespread hepatic cirrhosis, and by such marked constitutional disturbance as was found in the case under consideration

(4) Jaundice due to *biliary concretions or calculi* does occur and is of marked degree It may be present at birth or shortly afterwards The small mass found post mortem in the common bile-duct was so soft and moist, and so easily squeezed flat and broken up between the fingers, that it seemed of recent formation—possibly a few hours or a day or two before death—and could not, therefore, be considered as the initial cause of the hepatitis Further, above the mass there was no dilatation of the common bile-duct, and the gall-bladder itself contained very little bile

(5) The apparent familial tendency to jaundice might at first favour a diagnosis of *familial acholuric jaundice* The intensity of the jaundice, its rapid course and fatal ending, the small and cirrhotic liver, appear to eliminate this variety Unfortunately, the fragility of the red blood corpuscles was not determined

(6) *Infantile biliary cirrhosis* occurs chiefly in India, is familial, generally begins about the seventh or eighth month of life, and is accompanied by hepatic cirrhosis of an intra and inter lobular type The onset of the disease by the fourth day, its rapid development and ending, the small spleen and generalised pericellular cirrhosis, and the rarity *of its occurrence in this country do not favour this* as a diagnosis

(7) *Acute yellow atrophy* has been recorded as a possible cause of jaundice in the new-born, but there is little in the present case to suggest it

(8) Congenital obliteration or *stenosis of the bile ducts* is a rare anomaly It may be familial, and give rise to portal and biliary cirrhosis with a cholangitis affecting the small and large ducts and the gall-bladder There is fibrous thickening of the bile-ducts The lumen may be recognisable microscopically, but no epithelial cells are present There is an enlarged cirrhotic liver and a large spleen The case here considered bears a reasonably close *resemblance to this condition* The early, progressive, severe jaundice, the absence of pyrexia, the emaciation and hæmorrhages, and the enlarged cirrhotic liver might seem to settle the diagnosis A careful examination of the bile ducts, however, revealed no unusual narrowing or obliteration, the lumen, though small, being free from the liver to the duodenum, and the walls of the duct being normal on histological section Further, the first stool observed contained bile Thus, the anatomical condition necessary to establish this as a clinical diagnosis was found lacking on post-mortem examination The absence of a large spleen is incidentally an important factor against this as a diagnosis

(9) *Congenital syphilis* may appear a possible explanation *I have shown the liver sections to six independent* pathologists who have each pronounced the case on the histological evidence as being more or less characteristic of congenital syphilis The papular rash on the buttocks and the "old man" appearance might be possible factors in favour of this as a diagnosis Against congenital syphilis there is (1) the absence of spirochætes in the liver and spleen, (2) the small spleen, (3) the absence of "snuffles," (4) the negative parental Wassermann reactions, (5) the non-venereal parental history, (6) the absence of a history of miscarriages or still-births, and (7) the fact that a normal healthy child has since been born

Conclusion

It appears, therefore, that the evidence is so strong against each of the two most probable causes of death —namely, congenital syphilis or congenital obliteration or stenosis of the bile-ducts—that a definite diagnosis cannot be given It is suggested that no one of the nine conditions here briefly enumerated was alone operative or primarily responsible for death Further than that it is impossible to go with certainty It may be that the explanation is in the presence of some unknown toxin circulating in the blood of the mother during her pregnancy (or pregnancies) without apparent harm to her fully formed cells, and circulating in the fœtus, where it led to such a complete destruction of hepatic tissue that the condition virtually became incompatible with extra-uterine life For such a condition no postnatal treatment would be of any avail

The Debt on Westminster Hospital —During the present week an attempt is being made to clear off the debt of £17,000 The hospital, which was founded in 1719 with 12 beds, now has 230 beds, 100,000 out-patient attendances, and 17,000 casualties The week's series of events began with the festival dinner last Friday in the hall of the Inner Temple, presided over by the Lord Chancellor, the other guests including the Speaker of the House of Commons and the Master of the Rolls Since Monday last there have been daily health talks, the speakers for the week being Sir James Purves Stewart, Dr Adolphe Abrahams, Dr Donald Paterson, Mr Rock Carling, and Mr Arthur Evans On Monday there was a choral service at Westminster Abbey, with an address by the Dean, and on Tuesday Princess Arthur of Connaught opened a bazaar at the hospital On Derby Day there were collections at Victoria and Waterloo stations, and on Thursday a concert at the Central Hall The hospital has been open to the public on three afternoons when there were exhibitions of X ray and sunlight apparatus

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE

A MEETING of this Section was held on May 27th, Dr S MONCKTON COPEMAN, the President, in the chair

Dr W. S C COPEMAN read a paper on the

PROPHYLAXIS OF MEASLES

He quoted statistics proving that the severity of measles had been grossly underrated in the past The death-rate in institutions of the Metropolitan Asylums Board in 1912 had been 20 3 per cent under 1 year and 18 8 per cent. between 1 and 2 years Methods of prophylaxis effective in other exanthemata were less efficient for measles on account of its long period of incubation and four days of often undiagnosed invasion with maximum infectivity. Epidemics of measles provoked less interest than epidemics of diphtheria, scarlet fever and small-pox, though they were often more fatal Present methods of prophylaxis were more or less traditional and were not rigorously carried out Wheaton and MacNalty recommended compulsory notification, early visitation of the home, and provision of adequate home nursing and medical care If some means of producing immunity in the susceptible could be added to these methods they would help to control the epidemics which occurred every few years

Serological Methods

After outlining the history of active immunisation against measles, Dr Copeman went on to describe the five ways in which the serum of convalescents, and to a lesser extent of adults who had had measles could be used In an emergency citrated whole blood could be substituted for serum

(1) *Seroprevention* —Serum could be injected into a healthy child or into an infected child during the first five days of incubation producing a passive immunity lasting about a month A larger quantity was required for the infected child than for the healthy. Unfiltered serum was more potent than filtered The recommended dosage varied, but 6–15 c cm. were the limits suggested for an adult during the early days of incubation The dose had to be increased in direct ratio to the time of exposure to the disease.

(2) *Seroattenuation* —The serum might be injected into contacts after the sixth day of incubation Measles would probably develop, but would be modified in its course, and active immunity would follow the attack This was the method of election The illness following had no catarrhal symptoms, Koplik s spots high temperature or complications

(3) Injection of serum at the beginning of the period of invasion would not affect the course of the disease but the rash around the site of the injection would be blanched (Phenomenon of Debre)

(4) *Serotherapy* —Injection of the serum after the disease had declared itself had no apparent action

(5) *Serovaccination* —Injection of serum into the unaffected subject followed by inoculation with the virus produced active immunity with less danger than a natural attack

The essential points in collection and preservation of serum were that the donor should be over 10 years of age. tested for syphilis malaria and tuberculosis and should have had an unmistakable and first attack of measles with uncomplicated convalescence and completed defervescence 500–600 c cm of blood might be taken from adults and the donor must be watched for several days afterwards lest he be in the incubation period of some blood-borne disease The blood should be taken between the sixth and ninth days after defervescence, this being the period when it was richest in antibodies, and it should coagulate at room temperature, the serum being decanted aseptically and tested for sterility To standardise potency it should be pooled with serum from at least two other subjects, and to ensure purity it should be kept in an ice-chest for four or five days before use In the cold it retained potency for several months. If doubt existed of its sterility it might be twice heated to 50° C at 24-hourly intervals or one drop of 5 per cent carbolic acid could be added for every 10 c cm R Degkwitz had produced serum from sheep but this apparently only had an inhibitory action on the symptoms and would not replace human serum Recently Ruth Tunnicliff and A L Hoyne had reported good results with goat serum using the green-producing organism Seroattenuation had the double merit of being applicable during an epidemic and yet of producing active immunity Most of the results spoke emphatically for the value of seroprevention in measles Debre and Joannon especially reported the eradication of two epidemics at their outset in a Medan infant asylum where the mortality in previous outbreaks had been 70 per cent

A Scheme for Combating Epidemics

Dr Copeman then outlined a scheme which he had elaborated from the work of many authorities for dealing with epidemics of measles Our present aim was he said to prevent every case and we were singularly unsuccessful It would moreover, be unwise to attempt to stamp out the disease unless adequate artificial immunisation were enjoined for if it returned to virgin soil the result would be a tragedy like that of the Faroe and Fiji islands We should aim instead at control It was during the fatal first three years that we should prevent measles, postponing it till over 5 when few healthy children die The population under 3 was 6 per cent only of the whole and the incidence of measles at this age, despite the heavy death-rate was only 12–15 per cent. of the whole To concentrate on this fraction would need no greater organisation than the present system. The scheme would require a skeleton corps of trained public health workers who could call upon a large body of less specifically trained but still useful workers from other departments in a short time. Secondly it would require a knowledge of where all children under 3 years were to be found Compulsory notification would be necessary The centre of every unit should be a serum-collecting station with a small laboratory and waiting-room attached for choice to some institution where measles cases were available The unit would generally be a large town and the M O H the central authority. Between epidemics the corps would collect a store of serum and educate parents about the danger of measles under 3 and the means of preventing it. The chief available channels for this propaganda were the press private practitioners lectures and posters in streets hospitals centres &c The staff should possess a card index containing particulars of all children under 3 in their area · duplicate copies of birth certificates sent to the M O.H would provide information of 90 per cent of the true number of births

Discussion

The PRESIDENT mentioned the recent work of N. S Ferry and L W Fisher who claimed to have isolated a diplococcus causing measles Until this should be confirmed our ignorance of the bacteriology of measles made us dependent on convalescent serum for immunological methods

SIR GEORGE BUCHANAN disagreed with Dr W S C. Copeman s statements about present attempts to prevent measles, and upheld the view that it was better to have measles and get it over This had been strikingly confirmed by the experience of unsalted peoples, such as Highland troops in the war and the natives of Fiji who contracted the disease in a very severe and fatal form It should be warded off until after the third year of life and then got over under as good conditions as possible Yet the children of better-off people did not die in large numbers even under three He thought the serological method suggested by Dr Copeman very interesting and would like to see it tried over here, but questioned whether the public would ever allow another child's serum to be injected From the practical aspect it would be better to work up the goat-serum method if that were possible

Dr A Montague described the 1875 and 1903 epidemics in Fiji Between these two dates measles had been entirely kept out by careful restrictions In 1903, when 3000 people died the officials realised that a grave mistake had been made and decided to allow measles to enter freely Since then there had been some slow smouldering epidemics, but the disease had had no practical importance Their policy for the future was to allow it to do its worst

Sir William Hamer agreed that the present system in this country was not that of preventing children from getting measles Since the M A B organisation had been enforced the death-rate from measles had gone down by half, and this was not accounted for by the falling birth-rate It would probably go down a great deal more if all cases of measles could really be removed to M A B hospitals in the early stages Infection meant real and lasting protection throughout life, and as it usually occurred before the children left the infant schools education was not interfered with This was a point to be borne in mind Would they be assured of this if dealt with by Dr. Copeman's method ?

Dr R A O'Brien spoke of the difficulty of getting a supply of serum, and mentioned a few cases in which it had been tried with apparent success—almost entirely in the families of medical men Tuberculosis was not a real danger, and malaria was not of much importance in this country, it was very rare to have spirochætes circulating in the blood except in cases of florid syphilis, but nevertheless the Wassermann test should be done on all donors It would be easy for a medical officer of health to get a tested stock and to inform practitioners in his district that it was there for trial Pooled adult serum would be worth trying in the absence of convalescents The only work of real promise that he had seen was that of Tunnicliff, but it had not yet been widely confirmed Her antitoxin was being tried, but contradictory reports were coming in, and it was very difficult in practice to get satisfactory results from such an investigation

Dr J. D Rolleston referred to the grave mishaps in connexion with toxin-antitoxin treatment, but said he knew of only three deaths with serum and one case of tuberculous infection of the wound He thought the difficulty of getting the serum had been insufficiently emphasised He had tried the Tunnicliff serum on 12 cases, but the results had not been conclusive, some patients escaped infection, some had mild and some abortive attacks, but these occurred in untreated cases Dr O'Brien's cases did not therefore mean much The Degkwitz serum had been a universal failure and caused severe serum disease without protecting from measles In his recent monograph Debré had described the production of active immunity by injection of very dilute solutions of virulent measles blood He did not think immunisation necessary on a large scale, it was not needed in better class families, and in his experience measles was almost always a mild disease when it broke out in hospital wards

Dr A. S. MacNalty spoke of the difficulty of getting donors, in the recent outbreak of poliomyelitis he had completely failed to obtain any donors for immunisation purposes Dr Copeman's scheme would have to be correlated with existing measures, particularly those for nursing and the prevention of complications In French experience measles had not been a mild disease in hospitals

Fleet-Surgeon W E Home referred to an investigation on the American Army in Texas in 1915, where measles had been regarded as a respiratory disease, with a rash as sequela, and treated by increasing ventilation and by airing the bedding and clothing Among 12,000 well-disciplined troops who obeyed orders the incidence-rate had been 30 per 1000, among two or three thousand notoriously slack troops the rate had been 130 per 1000 The significance of the respiratory part of the disease might explain why it was mild in hospitals

Dr M B Arnold wondered why it was that measles and whooping-cough had been omitted from the list of notifiable diseases when the Act was formulated It was interesting to see how the mortality of the diseases included in the list had decreased, compared with measles, influenza, and whooping-cough

Dr Graham Forbes hoped that Dr Copeman's inquiries would result in a clear lead for public health authorities School closure had not been the method of dealing with measles epidemics since 1902, when a careful inquiry had been conducted at Woolwich, and it had been found that the exclusion of unprotected children was a better method Two or three years ago a further scheme of cooperation between school nurses, teachers, attendance officers, and medical officers of health had been inaugurated, and this very complete system had borne fruit in a diminished mortality In the quinquennial period 1911–15 the mortality had been 9500, in the next five years 5800, and, in the years since 1922, 3800 This efficient organisation for controlling measles in schools would be available for use if sero-attenuation offered itself as a help to the present system

Dr A M Leathem described a small experiment with Degkwitz serum carried out by the Medical Research Council, but cut short on account of the alarm caused by reports of serum disease Further work was to be done on monkeys in the autumn

Dr Clark Trotter emphasised the importance of nursing and care He described the severe measles contracted by a Newfoundland regiment

Dr Stella Churchill said that during an epidemic in Bermondsey 16 children out of 40 died in the local infirmary, while those who were nursed at home did better. One way in which practitioners could help was by insisting on proper nursing in the home, parents would not keep children in bed for measles if left to themselves She thought there would be great difficulty in persuading the public to submit to any more inoculation methods

Dr T S McIntosh said that measles and whooping-cough were the two diseases in which there could be no question that artificial immunisation was a satisfactory thing It was questionable in other diseases which many people managed to escape altogether Seroattenuation produced a controlled natural immunity, which, there was good reason to believe, was better than an artificial immunity Better still was the immunity of a natural attack, and the best method was to let children get the disease and reduce the mortality As long as human serum was the only method immunisation would not be of much practical value He asked whether the immunity proposed by Dr Copeman was to be active or passive

Dr W S. C Copeman, in reply, said that active or passive immunity depended on many factors Sero-attenuation was the only practicable method in an epidemic, but it was also desirable because passive immunity lasted only a few weeks Weakly children could be made passively immune and take their chance of getting active immunity during the next epidemic He had no intention of supplanting present methods, all the organisation he proposed was working at Woolwich, which merely needed serum to complete his scheme The scheme was, of course, voluntary, and presumably parents would give their own blood to immunise their children If the mortality were halved by good nursing it would still be 10 per cent, and that was higher than the mortality from scarlet fever, for which there was an elaborate scheme in force He had not had difficulty in getting donors The Debré phenomenon provided a rough method of testing the value of sera

ROYAL SOCIETY OF MEDICINE. SECTION FOR THE STUDY OF DISEASE IN CHILDREN

A MEETING of this Section was held on May 27th, when Dr J D ROLLESTON gave a presidential address on the Section and Its Work from 1908 to 1926 The Society for the Study of Disease in Children, founded in 1900, was, he said, incorporated in 1908 in the Royal Society of Medicine, which then consisted of 13 sections At the present time the Section ranked sixth in the number of its members among the 24 sections of the Society During the war it had been forced to diminish its activities The number of meetings in the session was reduced from eight in 1913–14 to five in 1914–15 and four in 1915–16, no special discussions were held, the provincial meetings were suspended, and owing to the paper shortage the number of pages allotted to the sectional proceedings was considerably curtailed England however, appeared to be the only belligerent country in which pædiatric meetings were held regularly during the war.

The President then reviewed the work of the Section under the three headings of (placed in order of importance) special discussions, exhibition of cases and specimens, and short papers

The attention of British pædiatrists had, he said, first been called to the following conditions by their exhibition at the Section· renal infantilism, blue sclerotics and brittle bones, treatment of congenital syphilis by salvarsan, Calvé's pseudo-coxalgia, mitral dwarfism, lipodystrophia progressiva, Kohler's disease, œsophagectasis, and the "*pink disease*" He deplored the fact that so few pathological specimens had been shown at the ordinary meetings of the Section This had been particularly noticeable since the war.

In conclusion, the President suggested (1) that at least one meeting in each session should be devoted to a special subject illustrated by clinical cases, (2) that surgical members should be urged to exhibit more cases; (3) that the exhibition of cases or specimens and communication of short papers relating to acute infectious diseases should be encouraged, (4) that more pathological specimens should be brought before the Section

MEDICO-LEGAL SOCIETY

A MEETING of this Society was held on May 26th, Dr A. S WOODWARK, the President, in the chair Sir G. LENTHAL CHEATLE opened a discussion on some

Medico-legal Aspects of Fracture of Bone

There was a fallacious idea, he said, that bones did not attempt to unite until about the fourteenth day after the fracture, whereas, in fact, there was no interval between the injury and the attempt to heal In spite of great differences in longevity, the bones of all animals took about the same time to heal He went on to discuss the evidential value of X ray photographs In a certain dispute about the length of a fractured bone, two X ray photographs taken on different days were compared in court For a comparison of X ray photographs to be of any value, however, as far as measurement was concerned the light, the plate and the patient had all to be in precisely the same position When an operation had intervened between the two exposures it was quite impossible for the second photograph to repeat the precise relationship of these three factors Any measurement between X ray photographs taken at different times was, therefore, useless If the light were not absolutely at right angles to the bone the shadow would be lengthened It was possible to make a difference of three to four inches by thus altering the angle of the light

Dr MORGAN FINUCANE remarked that the treatment of fractures and surgical injuries had been completely revolutionised In the old days fractures were kept immobile and movements were utilised late, and he wondered if the new methods were responsible for the comparatively large numbers of ununited fractures reported nowadays He had had recent experience under the Workmen's Compensation Act of the deformities resulting from the too early removal of splints and too vigorous massage These deformities were extremely important from the point of view of compensation because, although the patient might recover sufficiently for the employer to call him "fit for work," he would be relegated to light work and so rapidly pass into the ranks of the unemployed He agreed that facts might easily be misinterpreted if X ray photographs were not taken under ideal conditions Modern methods of team work in diagnosis had the disadvantage that the diagnostic training of the student was apt to be neglected, the general practitioner being reduced to a machine, and his value depreciated in the public eye In his opinion far too much significance and erroneous significance, was attached to X ray photography in diagnosis and still more in prognosis The ability of the rich to produce radiographic evidence was apt to be a grave injustice to the poor

Dr B O'CONNOR recalled his association with Lord Lister in the old Edinburgh Infirmary in 1870, and claimed the honour of having been the first person to demonstrate in a London hospital Lister's methods of treating surgical wounds Six weeks had then been generally considered to be the time necessary for a fractured bone to acquire some degree of firmness. Modern practice, so far as he knew, did not neglect the conditions under which healing took place He agreed that X rays were put to a good deal of misuse If lay people knew what X rays showed, well and good; but they were simply told by an expert that certain shadows meant certain things which they did not understand, and then they expressed opinions about a subject of which they knew nothing

Dr G SLOT referred to cases of habitual fracture. Not many cases of ununited fracture were seen nowadays in hospitals, he said, and when they did occur it was often because the patients themselves had tampered with their splints Many bad results were due to the neglect of patients to follow instructions Massage was of great help to surgeons The two great medico-legal difficulties connected with fractures were (1) the difficulty in country practice of getting an X ray examination, and (2) the difficulty of assessing the exact amount of pain that a patient felt Then there was the important question of arthritis—how far the fracture caused it Lastly, some fractures, especially those at the ankle, often occurred as sequelæ to an accident, and not at the time of the accident itself

Dr KNYVETT GORDON said that nobody could tell how long a given fracture would take to heal. It depended on the calcium metabolism of the individual, which in turn depended on various factors not easily estimated

The PRESIDENT remarked that some judges forbade X ray photographs to be produced by anyone but the person who had taken them This was a very important ruling, and one calculated to serve the ends of justice He spoke of the frequency with which radiologists gave conflicting evidence about the same pictures Many things could be read in X ray photographs The exact length of time it took a fractured bone to unite depended on factors of personal health, heredity, and the like The legal aspect of fractures did not end with union; if a joint were involved it was necessary to consider the man's capacity for work afterwards

Sir LENTHAL CHEATLE, replying, said that if a fracture did not unite within a reasonable time it had generally been treated badly He thought that a fracture healed most quickly if the limb were massaged and not moved Immobility and massage were not incompatible.

Reviews and Notices of Books.

AN OUTLINE OF ABNORMAL PSYCHOLOGY

By William McDougall M B , F R S , Professor of Psychology in Harvard College London Methuen and Co , Ltd 1926 Pp 572 15*s*

The publication of a book by Prof William McDougall is an important event in the history of psychology He takes his place among the few great writers in this science, not only by reason of his widely-ranging intuition, his clear incisive mind, and his genius for the practical application of what both these qualities teach him, but also because he can express himself in intelligible language The most formidable hindrance to the propagation of the doctrines of modern psychology has always been the failure of its exponents to make people understand what they are talking about Prof McDougall is gifted with the power to interpret for English-speaking readers both what he has made out of the teaching of other pioneers and what he has added to it from his own study and reflection. A few years ago, in his "Outline of Psychology," he gave the world an interpretation of the laws which govern the normal psychology of the human mind Now he extends his field to the consideration of mental disease, in a twin volume to the first, the two forming one complete treatise He has therefore taken an important step towards bridging the gulf between academic or speculative psychology, and abnormal or pathological psychology—the gulf between what ought to be and what is For no man is wholly sane or normal, and the knowledge of what ought to be is futile unless balanced by the patient and humble study of the ills which afflict in varying measure the mind of every man Hitherto the gap has remained practically uncrossed. The academic psychologists have concentrated on their laboratory experiments and the physicians on mental disease Freud's great essays in psychopathology merely made the dissension triangular, for he neglected not only academic psychology on the one hand, but also the proven facts of neurophysiology on the other Prof McDougall has here made a splendid attempt to bridge all three chasms, and no one could have better qualifications for the work of which this book is the expression and the fruit Prof McDougall is nearer to earth than Jung, but less rigidly mechanistic than Janet Holding the "dynamic" view of psychology, he believes in a force which manifests itself in behaviour, but, unlike the mechanists, he maintains the conative essence of this force All behaviour is, for him, directed towards an end The sources of power are the instincts, its channel the emotions, and its emotional-conative activity colours every event in mental life, even the most purely intellectual We are not, however, simply machines The structure of our minds has something in common with that of a complicated machine, but the machine has a controller, a driver, in the conscious self This "self" Prof McDougall wisely does not attempt to reduce , he leaves it as the lowest common denominator of the whole problem of life, as it has always been left in every metaphysic Of its existence he has no doubt, he is therefore sharply defined as an autist

It is not until the end of his book that we reach the definite statement of what he conceives to be the nature of human personality which he holds to be not simple, but multiple Every activity of the body and mind is presided over by a distinct personality, a "monad," which works to a definite purpose The mind is not a machine, with different parts, but a hierarchy consisting of an incalculable number of members, all related to one another in various kinds of function or degrees of command and submission, but all subject ultimately to the self, the conscious monad Every monad has its sentiments and ideas every monad draws power from the instincts and lives its own life, but the conscious self, fed by all the instincts and motivated by the self-regarding sentiment, is by nature intended to be the king of them all Functional disorder is the inability of a monad or monads to carry out their work efficiently, or the dissociation of a number of monads from the community, or the failure of the self to regulate the kingdom Schizophrenia, the psychological basis of dementia præcox, occurs when the kingdom has never been properly integrated by the formation of an adequately strong sentiment of self-regard This conception enormously simplifies much that has hitherto remained obscure

Prof McDougall covers the whole range of functional mental disorder, including even those conditions where the endocrine system is proved to have undergone some change, for he rightly holds that the two systems, glandular and nervous, react on one another to such an extent that the cause-effect relationship between them is indefinable in the present state of our knowledge He classifies his disorders into two groups those due to dissociation (hysteria) and those due to neurasthenia (anxiety, obsession) This agrees roughly with Kraepelin, and the association of the latter two, where Kraepelin distinguishes them, does not prejudice an accurate estimate of their nature He recognises that schizophrenia is not in itself a neurosis, but a defect upon which a neurosis of nearly any kind may supervene Of his attempts to bridge the gulf between neurology and psychopathology, perhaps the two most striking examples are his work on the extravert-introvert scale and his neurological mapping of the complex Jung distinguishes between introverts and extraverts, but makes no attempt to explain the difference McDougall says that every individual has a place somewhere on a scale, at one extremity of which is the ideal introvert and at the other the ideal extravert, and that life tends to push everyone towards the other extreme from that near which he starts That the introvert has relatively low and the extravert relatively high synaptic resistance is shown by the difference in their reaction to various ocular tests Alcohol, he finds, encourages extraversion and the alkaloids introversion The extravert's brain is more liable to morbid dissociation than that of the introvert, because it is normally in that state of relative dissociation which the introvert's brain reaches under alcohol The position of any subject in the scale is a function of some quite general property of his nervous system and is probably determined by "some chemical influence like that of a hormone or endocrine secretion, or some complex chemical resultant of the general metabolism" The neural scheme of the complex is a masterpiece of inductive thought, and postulates what amounts to the short-circuit of a given system of cognitive cortical dispositions away from all other systems

It is possible to criticise a work of this magnitude and authority only with the greatest diffidence The bias of the author's interest is on the side of the dissociative disorders, and this has led him to allot a large amount of space to their discussion and to the description and consideration of hypnosis, which he regards as one of the most valuable means to the experimental study of the mind But he has allowed his chapters on hypnosis and suggestion to become separated from those on alternating and multiple personalities, which is rather confusing for the student It is a pity, also, that he has to confess himself unable to follow Jung's type-classification, which has simplified psychology for so many people A graver defect is that far too much space is occupied with destructive criticism of the views of Prof Freud An analysis of the Freudian teaching is an indispensable part of the book, but in thus condemning so many of the implications and inferences of the pan-sexual theory Prof McDougall has gone too far to the other extreme, and unduly restricted his view of the scope of the sex-instinct in human motives Nevertheless, the book provides an honest and clear-sighted review of the whole field of psychopathology, *expressed in a* medium of great power, persuasiveness, and lucidity

Clinical Physiology

By R J S McDowall, D Sc , M B , F R C P Edin , Professor of Physiology, King's College, University of London London Edward Arnold and Co 1927 Pp 424 21s.

THOSE whose study of physiology took place some years ago, whether they be senior students, practitioners, or consultants, should welcome Prof McDowall's book For he covers an enormous subject with a simplicity of language and with such thoroughness that the clinician will find interest in numerous chapters whatever may be his particular bent It is inevitable that such a work should be uneven, and if we would cite the chapters dealing with the circulation, special senses, and nervous system as being of especial excellence, it is but right to point out that those dealing with the kidney and the endocrine glands are of a lower standard The foreword by Prof Halliburton, in which he extols the value of physiology to the physician, very rightly indicates the value of the book as a whole

Physiology and Pathology

Traité de Physiologie Normale et Pathologique Edited by G H ROGER Vol VII , Blood, Lymph, Immunity Paris Masson et Cie 1926 Pp 502 Fr 65

THE energy of Prof Roger is inexhaustible He has organised the production of a great work by many authors in 11 volumes which shall survey physiology in a most catholic fashion, taking into its view invertebrates at one end of the scale and sick persons at the other. It is intended to be a book which shall secure that the doctor's work is founded on a broad biological foundation and that the biologist shall know something of the valuable lessons which practical medicine has to teach him Such an ideal cannot, of course, be fully realised on earth, but judging from the present volume the work will be of use and interest and well worth reading, if only because the French points of view differ in such a salutary way from those to which we are accustomed The most notable sections in this instalment are those by J Bordet (95 pp) on immunity antigens and antibodies which is a first-rate summary of the mature views of a master, and by Ch Achard (56 pp) on tissue fluid or, in the convenient French terminology, the "systeme lacunaire" Transfusion and its indications are dealt with by P Emile-Weil, and L Cuénot describes the respiratory proteids of the invertebrates The rest of the blood is discussed by J Jolly and others, and there is a special section on hæmorrhage , the general level of this series of articles is not particularly high Other chapters cover lymph and lymphatic glands, and A Besredka discusses anaphylaxis along lines which he has made familiar

Physiology and the Surgical Treatment of Pain

Die Leitungsbahnen des Schmerzgefuhls und die chirurgische Behandlung der Schmerzzustande By Prof Dr O FOERSTER, Breslau Berlin and Vienna Urban and Schwarzenberg 1927 With 104 illustrations Pp 360 M 19 50

AMONG the select company of neurological surgeons Prof Foerster of Breslau holds an honoured place, gained not merely by his clinical experience but by his able researches as a physiologist and experimentalist These he brings into contribution in this noteworthy monograph on the physiology of pain and its surgical treatment

Possibly the most interesting section deals with the nature of pain and its physiological correlates A careful review of the problem reveals not a few questions in respect of which finality is far from having been reached, notably that of the possible interassociation of the vascular system with the sensation of pain The author here adduces fresh evidence in favour of such a connexion, to which the neurologist would do well to attend A minute study is also made of the phenomenon of hyperpathia, by which is signified an appreciation of pain in consciousness altogether disproportionate to the stimuli originally arousing that sensation Next, the anatomical basis of pain-conduction is subjected to a most detailed scrutiny, and various gaps in our knowledge are pointed out Data derived from clinical medicine and surgery are underlined as suggesting that some impressions concerned with the appreciation of pain pursue a somewhat devious route by the sympathetic chain before entering the cord at high levels, and an interesting study is made of the possible differential diagnosis between root pains and posterior horn pains —a point of some practical importance In the second part Prof Foerster examines at great length the appropriate surgical treatment of such difficult problems as the visceral crises of tabes, visceral neuralgia in general, amputation neuromata, varieties of radiculitis, headache, and so on In all of these he brings to bear for their solution a fine combination of physiological knowledge and clinical acumen, to which we may believe his technical skill will add in practice a component of value There is food for thought in this scholarly contribution to the perennial topic of the successful treatment of painful conditions, and its appeal is unusually wide It is just as meritorious for its suggestiveness and the sidelights it throws on still vexed problems as for its accomplishment

The Student who Smokes

By J ROSSLYN EARP London H K Lewis and Co , Ltd 1927 Pp 61 5s

LAST year some £53,000,000 were added to our national receipts by our habit of smoking Does taking tobacco do us any good—physically, mentally, or spiritually ? Does it do us any harm ? Dr Earp has endeavoured to advance towards an answer to these very difficult questions by intensive study in a limited field, and has analysed the habits of the students at Antioch College, Ohio, in relation to their physical and intellectual performances He subjects his data to critical statistical examination (the rationale of which he also explains for the uninitiated) and discusses them with a fairness and absence of bias which might with advantage be imitated in more pretentious works on social questions. One conclusion emerges quite clearly that the habit of smoking is associated with inferior scholarship. He shows also that students who inhale are inferior to those who smoke less thoroughly Apart from this piece of evidence, there seem to be no satisfactory grounds for choosing between the alternatives that scholastic inferiority is due to smoking, that smoking is due to scholastic inferiority, and that both are due to the nature of the individual The only thing to be done is to try experiments on a large scale , we hope this will be achieved

Fermentation

Le Problème des Fermentations Les faits et les hypothèses By M SCHOEN, Chef de laboratoire à l'Institut Pasteur Paris Masson et Cie. 1926 Pp 199 3s

THE problem of fermentations, as M Schoen points out, is of *unceasing* interest, and although so many papers have been written on the subject by leading workers in the field of biological chemistry, a vast area still remains open for investigation M Schoen reviews the work which has already been done on this problem , unfortunately, however, his monograph contains more hypotheses than facts He opens with an account of the main points of Pasteur's work and shows how his theory that fermentation is *the result* of life without free oxygen, and that, besides the two principal products of fermentation, alcohol and *carbonic acid*, glycerine and succinic acid are also formed, has been confirmed by experiments The monograph proceeds to consider chiefly alcoholic fermentation, but bacterial fermentation is not neglected, and the author shows how the different types of fermentation are united

The book forms a useful review of the work on the subject, as Prof Fernbach says in the preface, to keep in touch with continuous scientific developments it is necessary from time to time to look back on the work already covered, and M Schoen's monograph will, therefore, be of service to those who are interested in the question of fermentation from any aspect.

DRUGS AFFECTING THE HIGHER BRAIN CENTRES

Phantastica die betaubenden und erregenden Genussmittel Second enlarged edition By Prof Dr L LEWIN Berlin Georg Stilke 1927 Pp 465

THE main title of this book can convey nothing to English ears, and the subtitle, though more suggestive, is difficult to translate satisfactorily The book itself, however, has well-defined limits It treats on all drugs that affect the higher brain centres, whether these drugs be taken for medicinal purposes or for pleasure Morphia, cocaine, Indian hemp, alcohol, hypnotics, camphor, caffeine, and tobacco, with their parent drugs and their derivatives, are discussed at length, as well as many less known drugs with similar actions The book deals, then, with habit-forming drugs, it is largely a warning against the use of such drugs, and depicts in ghastly colours the results of drug addiction The work is written in popular terms as a further subtitle "für Ärzte und Nichtärzte" suggests, neither the medical nor the psychological side of drug addiction is treated in a deeply scientific manner, but there is much interest in the history of the drugs, in the comparison of modes of use and of symptoms, and in the accounts of drugs used in savage countries and those used for similar purposes in civilised lands The series of substances dealt with vary widely in action, but are connected to form a well-defined group, the use and abuse of members of this group afford one of the great problems of modern times, and a comprehensive work of this kind has therefore a real interest

TEXT-BOOK OF MATERIA MEDICA FOR NURSES

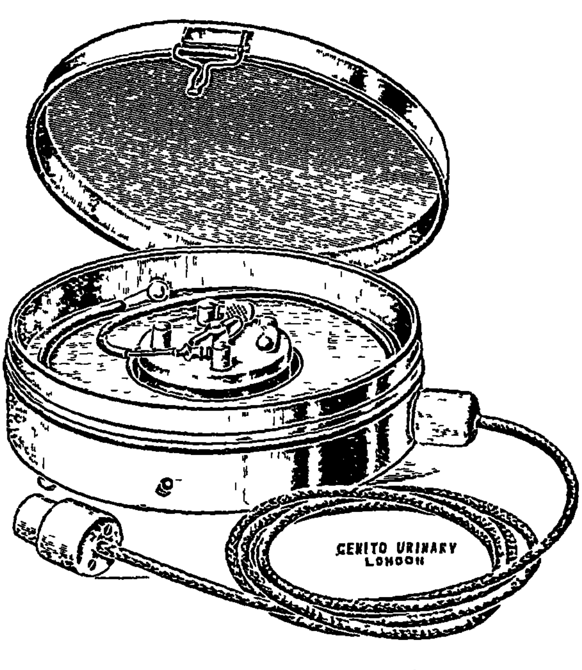
Eighth edition By LAVINIA L DOCK, R.N, and JENNIE C QUIMBY, R N London and New York G P Putnam's Sons 1927 Pp 317 7*s* 6*d*

THE subject of materia medica is evidently taught to nurses in America in far greater detail than in this country We should be happy if the medical student knew all that is in this book Its general arrangement is according to the drugs acting on different systems of the body; there are also notes on drugs generally, poisons, chemistry, physiotherapy, laws relating to dangerous drugs, watering-places Most of the matter written under these headings is clear and good. The dose of cocaine 2 gr, given on p 40, seems high; the doses of tuberculin apparently intended to represent the apothecaries' and the metric system—namely, 1/250–1/65 gr and $\frac{1}{2}$–1 c cm—do not seem to correspond Though most of the pictures are good we should certainly fail to recognise poppy and monkshood from the prints given Many of the European watering-places mentioned are of small importance Generally, the book is well expressed, neatly published, and quite interesting.

New Inventions.

AN ELECTRIC STERILISER FOR URETERAL CATHETERS

THE steriliser consists of a circular box, 7 inches in diameter and 2 inches deep, with hinged lid. A small container for formalin tablets is fixed to the centre of the base of the box It has an air-tight lid, which is held in position by means of a winged nut, and an inlet for compressed air which terminates on the outside of the box in a valve Two electric heaters lie immediately below the formalin container They are wired up to a special plug fitting in the side of the box This plug can be connected to the ordinary domestic electric supply, and either direct current or alternating current can be used Surrounding the formalin container is an annular tray on which the catheters rest Below the tray are racks for holding a 10 c cm Record syringe, spare metal caps, and a wire for cleaning the catheter nozzles, all of which are sterilised by means of the formalin vapour The lid of the formalin container is furnished with four metal nozzles, to which the catheters are attached by means of adjustable connexions Each catheter is inserted, before sterilising, into a rubber tube, long enough to enclose it completely The end of the tube where the eye of the catheter lies is closed by a wooden peg The proximal end of the catheter is then attached to the nozzle on the lid of the formalin container by means of the adjustable connecting piece and the apparatus is then closed and connected to lamp socket or wall plug When the current has been turned on for 20 minutes and the formalin vapour well liberated from the tablets, air is pumped into the formalin chamber through the valve in the side of the steriliser It forces the hot concentrated formalin vapour through the lumen of the catheter, down to its eye From this point it must travel backwards between the catheter and the rubber tube before it can escape into the body of the steriliser It has been found experimentally that catheters infected with non-sporing organisms (*Bacillus coli*, staphylococci, and streptococci) are sterilised even when air has *not* been pumped through the steriliser, but to kill the spores of the *Bacillus subtilis* it was necessary to increase the force and volume of the current of formalin vapour through the catheter by means of the air pump



This apparatus has been made for me by the Genito-Urinary Manufacturing Co, Ltd, 64, Great Portland-street, London, W.

J SWIFT JOLY, F R C S

THE LANCET.

LONDON, SATURDAY, JUNE 4, 1927

ROYAL COLLEGE OF SURGEONS OF ENGLAND POSITION OF THE MEMBERS

THE direct representation of Members on the Council of the Royal College of Surgeons of England, which has been advocated steadily for years in these columns, is forming the subject of an investigation by the Council, who have invited from the Fellows an expression of individual opinion The views of the Members have been registered clearly and frequently in the press, and at general meetings of the Fellows and Members Those engaged actively in promoting the direct representation of Members on the Council may not form a large numerical proportion of the Members, but the recognition by the Council that this fact provides no valid argument for a refusal of discussion will be welcomed as fair and statesmanlike The protagonists of a real movement are often few in number, but, if the movement is real, they speak and act, at least equally often, for large numbers who will benefit by any success which may attend their efforts In many discussions of the arguments for reform ranging over three-quarters of a century, we have had to record maladroit handling of the different situations as they arose, both by the friends and the enemies of the constitutional change which is sought We have now a new situation, for the first time the move comes from the central authority of the College

About 30 years ago a majority of the existing Council had expressed themselves in a greater or less degree, privately or publicly, as well disposed to the views placed before them by both Members and Fellows for extending the rights of the Members But benevolent intentions are prone to disappear partly as the results of further reflection, and more often—and also more creditably—help that has been promised falls away when the champions of the change are unable to formulate a scheme by which their objects can be obtained in a practical way A discovery of the method is still awaited by which representation of the Members on the Council can be brought about without undue disturbance of the functions of the College, as set out in the charters—namely, to romote the science of surgery and encourage in cademic and professional ways its methods of ractice Many declarations have been heard and ave been received with sympathy and applause, to e effect that it is anomalous in these days for a rporation to be governed without reference to the ajority of those who form it, but so far the concrete ggestions for altering the position have been unable survive criticism It is legitimate to hope for a fferent result from the present action of the Council asking the Fellows, who have elected them to their ats, for a definite expression of opinion, especially cause the Council has placed before the Fellows detailed statement of the situation That nonssumus attitude has gone which was founded on the sumption that, because only a few Members voiced y demand for the right to vote, an inquiry into the stice of the demand was unnecessary, while the llows will be dealing with the matter after being rnished with the basis for forming their judgments The statement placed before the Fellows commences with a brief historical sketch of the incorporation of the College, of the granting of its charters, and of its functions, it then sets out the financial arrangements made with the Royal College of Physicians of London for a Joint Examining Board, and details the rights and privileges of the Members and Fellows as at present enjoyed Here it is indicated that the positions of both are identical, save in the important matters that the Fellows vote at the election of members of the Council, they only are eligible to sit on that Council, and they only can be members of the Court of Examiners, or appointed examiners in anatomy for the Fellowship of the College and in the surgical section of the Board of Examiners in Dental Surgery There follows an enumeration of the claims of the members, as put forward since the institution of the annual meeting of Fellows and Members in 1885, from which date resolutions have been passed almost every year in favour of giving Members some form of direct representation on the Council The list of claims is published with the remarks of the Council directed to the substance of each claim appended Some of the statements which have been repeatedly made in behalf of the Members are to some extent traversed by the Council, especially is it brought forward that the majority of the Fellows taking part in the elections of the Council are themselves in general practice, so that the interests of Members who are in general practice may be taken to receive the care of the Council, as far as the charters empower the College to promote such interests It will be unfortunate if the statement of the Council to the Fellows is regarded by the Members as an adverse prejudgment of their claims, just as it will be unfortunate if the Fellows of the College resolve to give their votes without looking at all the circumstances It may be that some parts of a strong demand for reform have no historic basis or have been made the subject of exaggerated dialectics, but these are not things which should determine inaction Opportunities of progress must not be sacrificed out of any considerations of precedent We hope that the vote of the Fellows will be a large one, and that the result will be a working scheme for the effecting of the change that is sought The difficulties of producing such a scheme will be many and far-reaching, but they will not be insuperable if the Council receives a clear instruction from the Fellows to proceed

◆

LEGAL LIABILITY IN CERTIFYING INSANITY

TWO judgments of particular concern to the medical profession were given on May 27th, both relating to the legal liability of a practitioner to be sued for alleged negligence in certifying a patient to be a lunatic The first in importance was the final decision of the House of Lords in the protracted litigation of Harnett *v* Fisher, whereby Dr FISHER succeeds, and the previous judgments in his favour by Mr Justice HORRIDGE and the Court of Appeal are reaffirmed The second case was that in which the jury gave Mrs DE FREVILLE a verdict of £50 damages in her action against Dr A V DILL Certain legal points remain to be argued here in the light of the review of the law by the House of Lords in Harnett *v* Fisher, Dr DILL has lost upon the issue of fact, but the comparatively small amount of damages awarded is significant, the main interest of the case is the sympathetic understanding of the practitioner's difficulties in lunacy matters which is revealed in Mr Justice MCCARDIE's summing-up to the jury

The legal issue in Harnett *v* Fisher is well known Mr Harnett, who argued his appeal in person and well, was certified to be a lunatic on Nov 10th, 1912 He issued a writ on May 31st, 1922, with the result that he was awarded £500 damages, the jury finding that he was not of unsound mind when certified and that Dr Fisher had not acted with reasonable care in certifying him But there was one objection to this result which proved fatal to Mr Harnett's claim The Statute of Limitations, passed more than three centuries ago, enacts that an action of this kind must be begun within six years of the existence of the cause of action The object of the Act, as Lord Sumner observed, is to protect defendants against belated claims—not merely defendants who have a good defence and to that extent need no protection, but also defendants who have not a sufficient answer or who, owing to lapse of time, cannot count on making it Mr Harnett's action was statute barred, he had not begun it within the six-years time limit It is true that the statute contains an exception in favour of persons who are under a disability and specifically names amongst these any person who is *non compos mentis* Mr Harnett, however, could not bring himself within this exception It had been of the essence of his claim, and the jury had found in his favour, that on the day when Dr Fisher certified him he was of sound mind, it was not established that he had ever been otherwise If he had never been *non compos mentis*, then the six year time-limit ran from Nov 10th, 1912, and his action, begun too late by several years, must fail Mr Harnett argued that, under and for the purposes of the Lunacy Act, he had been made a lunatic and was treated accordingly, both in person and property, and that, for the purposes of bringing an action, he was as much disabled as if he had in fact been *non compos mentis* He urged that the statute should be liberally interpreted so that his practical disability should be deemed a disability under the Act Against this argument it could have been said that, about a month after the reception order was signed, Mr Harnett was allowed to leave the asylum provisionally and was actually at large for two days, moreover, after his return he frequently communicated with his solicitor and occasionally saw him personally But the House of Lords brushed these considerations aside The question was not one of Mr Harnett's status as a lunatic, but of his mental condition of sanity or insanity, and this point had been finally disposed of by the jury's verdict in his favour The House of Lords was not concerned to justify what Parliament had enacted in 1623, or to regret that it had gone no further to assist persons in Mr Harnett's situation The tribunal had merely to interpret the law, and on that interpretation Mr Harnett could not succeed

There remained one subsidiary point which is important to all practitioners who find themselves in Dr Fisher's position During the argument on March 3rd Lord Blanesburgh suggested that the wrong statutory limitation had been relied upon by Dr Fisher His lordship remarked that possibly the Jacobean statute of 1623 had nothing to do with the matter. Section 331 of the Lunacy Act of 1890 prescribed a special period of limitation in the case of an action under Section 330, and that period was one year after release On this hypothesis Mr Harnett's action was not time-barred, as it was begun seven months after he regained his liberty It was true that Section 331 of the Lunacy Act was repealed by the Public Authorities Protection Act of 1893, and there was some question of the absolute extent of the repeal Assuming that the repeal was complete, then the law applicable was the Public Authorities Protection Act which prescribes a special time limit of six months, and again the result was that Mr Harnett was out of time Lord Blanesburgh referred to this point in his judgment on May 27th, in which he reached the same conclusion as the other members of the tribunal, but by a different line of reasoning The House of Lords allowed Dr Fisher to amend his defence so as to plead the Public Authorities Protection Act of 1893 as well as the statute of James He thus had two strings to his bow Lord Sumner, however, and others of their lordships disagreed with Lord Blanesburgh and regarded the 1893 Act as inapplicable, the Act of 1623 being the Act which really applied The reasoning here deserves close study. The Public Authorities Protection Act applies to actions brought for doing, or neglecting to do, an act under any statute of the kind described—in Dr Fisher's case the Lunacy Act The only act by Dr Fisher of this nature was the signing of the certificate in the prescribed form But, said Lord Sumner, the gist of Mr Harnett's claim was not the signing of the prescribed certificate, but the alleged lack of care in examining his mental state and in forming an adverse opinion about it The negligence could only arise in that connexion, it was breach of a common law duty, not breach of a statutory duty, the negligence, if any, was that of a medical practitioner acting in the course of his private practice Anything else was either a separate cause of action under the Lunacy Act for which no damage could be recovered, since the detention order was the order of the justice and not of the doctor, or else it was a mere item in the damages claimed as flowing from the negligence This view expressed by Lord Sumner usefully underlines the judicial responsibility of the magistrate which is by statute interposed between the alleged lunatic and the certifying doctor, but the implications of the argument are far-reaching It makes a considerable difference to the practitioner whether he is protected by a time-limit of six years or by one of only six months Great interest will therefore attach to any further explanation of the legal position which may be forthcoming if Mr Justice McCardie is asked to consider the application of Harnett *v* Fisher to the case of de Freville *v* Dill

If Parliament contemplates any change of the law of medical liability in the certifying of insanity, it will no doubt be contended that Mr Harnett was unfairly treated in receiving all the practical disabilities of the status of lunacy and yet being debarred from any legal concession At the same time our legislators must not forget what Mr Justice McCardie has been saying to the jury in the action against Dr Dill Litigation of this kind has not been infrequent in recent years, and medical men may decline to give certificates if they thereby become subject to actions in the law courts and are embroiled in embittered family strife with which they have no concern It is a serious matter, said the learned judge, that the Lunacy Acts contain no definition whatever of insanity, unsoundness of mind or lunacy, they provide no test, they set no standard, and they give no guidance The keynote is first the welfare of the patient, and secondly the public safety which may require that the patient be put under care and treatment "A doctor who is called in to deal with an alleged lunatic is dealing with the most difficult subject known to the medical profession, the forms taken by unsoundness of mind are so many, diagnosis and classification are difficult, and not only do the forms and symptoms vary, but each varies in degree, in gravity, and intensity, symptoms and outbreaks may be intermittent and may vary year by year, month by month, and day by day" Some observations by Lord HALDANE in Everett v Griffiths were opportunely quoted —

"To-day he is sane in his conduct and probably was so very soon after the occurrences in question But the point is whether at the time of those occurrences he had so lost his capacity for self-control as to be, temporarily at least, to all appearance of unsound mind within the meaning of a statute which takes account of his relations to others as well as to himself"

The jury, added Mr Justice MCCARDIE, must remember the Lunacy Acts have to be administered, and certificates have to be given, not only by London specialists and other experienced practitioners in great cities, but also often by ordinary country doctors It is one thing to come to a decision upon the accuracy of certification after a seven days' hearing in court with evidence on both sides and the assistance of experts and counsel, it is another thing to come to a decision in a room in a country vicarage "A general medical practitioner gives no warranty of special skill or knowledge, he is bound to exercise due care, having regard to the skill and knowledge which he actually possesses" Fortunately, in Mrs DE FREVILLE's case against Dr DILL any suggestions of bad faith that might have been made against the defendant were withdrawn before the case was left to the jury The mere fact that such suggestions can occur will make medical practitioners the more reluctant to run the risks of undertaking certification under the Lunacy Act unless the medical profession is to be assured of a reasonable immunity under the law

◆

THE INTER-STATE ASSEMBLY

THE Inter-State Post-Graduate Assembly of North America have held their annual congress in London this week The session was opened with addresses by the Marquis of READING and Lord DAWSON OF PENN, and as will have been gathered from the announcements last week of the various functions, the visiting doctors from the States and from the Dominion of Canada have been offered in London large facilities for a post-graduate gathering Our medical organisations and institutions have coöperated to welcome the visitors from scientific and social aspects alike The lectures delivered during Wednesday, Thursday, and Friday (to day) at Dartmouth House, Charles-street, the headquarters of the English-Speaking Union, were representative of British practice to-day in medicine and surgery, and the opportunities afforded to the members of the Congress for seeing the theories exemplified and the techniques practised at the metropolitan hospitals have been numerous On each day special programmes have been arranged, to be carried out at many of our best known general and special institutions, where the staffs have attended to give appropriate demonstrations, while the range of operations performed for the instruction of the audiences was large and instructive The importance of these gatherings is, of course, proportional to the number of those who attend, having before them the great object of scientific coöperation The attendances at receptions and the inspection at museums and collections should be treated as agreeable interludes, the real business of these international assemblies is to prove that medicine knows no national confines, and that all its followers have something to learn from and something to teach to their colleagues

Annotations.

"Ne quid nimis"

CREMATION

THE Cremation Society of England, of which Prof Chalmers Mitchell is chairman and Dr H T Herring hon secretary, is taking steps to popularise the practice of cremation in this country Dr Herring opened a discussion on the subject at the recent sessional meeting of the Royal Sanitary Institute held at Bath At the Annual Conference of Cremation Authorities, held in Birmingham on May 25th, several speakers, including Principal C Grant Robertson and Sir John Robertson emphasised the economic arguments in favour of cremation The medical profession does not require to be convinced of the advantages of cremation on hygienic and æsthetic grounds, but the great cost to the community of earth burial is not sufficiently realised An enormous area of land which is badly needed for building sites, allotments, food production, and recreation must be set apart for cemeteries It is usually estimated that from a quarter to half an acre is required per 1000 inhabitants and that this suffices for only about 14 years, stated in another way, with a death-rate of 500,000 per annum, the area occupied for burial purposes would amount to 500 acres yearly in this country. The cost to the ratepayers amounts to hundreds of thousands of pounds a year, for most authorities have a considerable annual deficit on their cemeteries: in Sheffield the loss amounts to £6000 per annum, in Manchester to £5736, in Blackpool to £4411. A year ago Sir Kingsley Wood, in answer to a question in the House of Commons, stated that the total sum which local authorities in England have been authorised to borrow for the provision of cemeteries during the preceding period of seven and a half years was £1,248,905 The burden on the living increases in geometrical ratio, and before many years municipal authorities will be compelled to face the possibility of refusing facilities for burial Experience abroad, notably in Switzerland and Czecho-Slovakia, shows that the practice of cremation, when recognised by the State, is accepted as a substitute for burial without question Municipal crematoria are for the most part self-supporting and if cremation were widely adopted the individual expense would be greatly reduced

The only serious argument against cremation is the alleged danger of destroying the evidence of crime in cases in which foul play may have caused death Experience and authoritative opinion show that the argument has no substance There are now 16 crematoria in England and Wales, and more than 37,000 cremations have taken place, yet in no case has any question subsequently arisen as to the cause of death. The stringent requirements which must be complied with before a body is cremated include the production of three statutory certificates and declarations, from the executor or nearest relative, the medical attendant, and an independent medical practitioner of standing Dr Herring has recently appealed to medical practitioners[1] generally to qualify for the position of granting this second certificate Considerable powers are vested in the medical referee appointed by the Cremation Authority, who alone can give the order for cremation to take place He is enjoined not to allow the cremation to proceed unless he is satisfied that the death has been duly registered by the production of a certificate of death, that the application and certificates are in order, that due inquiry has been made by the persons giving the certificates, and that the fact and cause of death have been definitely ascertained In particular, if the cause of death given in the medical certificate is such as may be due to poisoning, violence or illegal operation, to privation or neglect, he shall require a post-mortem examination to be held, and if that fails to reveal the cause of death shall decline to allow the cremation unless an inquest be held and a certificate given by the coroner He may in any case decline to allow the cremation, and is not bound to state his reason for refusal Lord Salvesen, who speaks with high judicial authority, considers these requirements so stringent as for all practical purposes to exclude the possibility of a body being cremated which has been the victim of foul play "No person," he stated in his address at the Birmingham Conference, "who had been guilty of poisoning the deceased would ever resort to cremation as a means of concealing his crime If he was in collusion with the medical attendant, or had managed to evade his suspicions, he would scarcely run the risk of an examination of the deceased by an absolutely independent official, who might report that a post-mortem examination was required to disclose adequately the cause of death and whose duty it is to set about inquiries which, if there had been foul play, would almost inevitably reveal any suspicious circumstances attending the death Lastly, he would have to face the possibility of the medical referee requiring a post-mortem examination to be held, which in the case of mineral poisoning would at once reveal the cause of death" Contrasting these requirements with those for ordinary burial, he added "A person who wished to conceal that the deceased person had perished from foul play would have no difficulty in many cases in obtaining a burial certificate, which affords a very inadequate safeguard against the body being put under the earth without the cause of death having been accurately ascertained"

---

[1] THE LANCET, May 14th, p 1035

At the present time, as the Registrar-General's figures show, some 5000 deaths a year are not certified by a registered medical practitioner at all, and in only about 40 per cent of the cases of death certified have the medical men seen the body after death Both the cause and the fact of death must be verified in every case before cremation is permitted

VOLUNTARY SEXUAL STERILISATION

ADVANCED proposals for legalising voluntary eugenical sterilisation are set out in an article by Mr H H Laughlin, of the Carnegie Institution of Washington, published in the *Eugenics Review* of April The author logically points out that laws for sterilisation are a mere extension of the principle of statutes which authorise the segregation of the insane and feeble-minded in custodial institutions, that on the long view of racial aspects sterilisation is fully as important as segregation, that voluntary sterilisation, while it might well be encouraged, must be subject to some measure of social control to prevent abuses, and that there already exist analogous laws governing surgical operations under which abortion is prohibited except for therapeutic reasons After tabulating the classes of defectives and others which should not be allowed to reproduce, and assigning in each class the responsibility for the initiative to prevent reproduction, Mr Laughlin formulates a draft statute for the control of voluntary sterilisation The main safeguards in his proposals are three First there should be a signed and sworn statement by the particular subject (or, if the subject is under age or otherwise incompetent, by the subject's parent or guardian) testifying to the belief that he possesses hereditary qualities of which the propagation would tend to lower the inborn hereditary standards of the nation Secondly, no surgeon is to operate for the purpose of sexual sterilisation unless he has been furnished with a second document signed and sworn by a licensed medical practitioner or by a trained biologist possessing approved qualifications, to the effect that the signatory has investigated the heredity of the particular subject and has found that he has hereditary qualities which, in the investigator's opinion, would tend to lower what have already been described as the inborn hereditary standards of the nation Thirdly, the surgeon would be required to make a return as to the nature and date of the operation, the name of the patient, and the surgical and physiological result All other sexual sterilisation by surgical or medical means would be prohibited except for therapeutical purposes as interpreted by established surgical or medical practice

These proposals will have their value as propaganda to draw attention to eugenic ideals, but it is safe to predict that it will be a long while before an Act of this nature is found in the English statute-book. Recently a mild endeavour to secure the better segregation of defectives has been resisted in Parliament on the ground that it is a gross infraction of the liberty of the subject, and even on the further ground that it is an objectionable piece of class legislation It is indeed doubtful whether this country is more ready to contemplate proposals for the control of voluntary sterilisation than to impose any form of compulsory sterilisation upon degenerates even after the most careful judicial and medical inquiry We are still in some uncertainty as to the working of the laws in certain American States where compulsory sterilisation is authorised Sterilisation does not destroy sexual impulse It may even do harm by creating a false atmosphere of security in which defectives may be allowed at large when they should be segregated

METAL FUME FEVER

THE occurrence of chills among brass-founders has long been known, and the name of "ague" given to these attacks denotes that they occurred in the Middle Ages when tertian and quartan fevers were indigenous, and the term was still current Brass is an alloy containing about two parts of copper and one of zinc Copper melts at 1080° C, 300° higher than the temperature at which zinc becomes volatile The fact that dispute exists as to whether or not copper is toxic makes it certain that this metal does not possess any pronounced poisonous effects Zinc is also recognised as non-poisonous in itself, but when volatilised it combines with oxygen to form an oxide, to the inhalation of which the attacks of brass-founders' ague have long been ascribed in the trade The whole matter has recently been under investigation in the Harvard School of Medicine Evidence has been acquired not only that zinc possesses no toxic properties, but even that it occurs normally and regularly in the various organs of the body; in suitable dilutions it can be used as a stimulant to vegetable life Further researches are reported in papers which have appeared in the *Journal of Industrial Hygiene* for March and May Two investigators submitted themselves to freshly generated fumes of zinc oxide, which they inhaled while in a cabinet containing known amounts. The one inhaled during five minutes some 48 mg of zinc, of which about 24 mg. were retained, the other in 12 minutes inhaled about 74 mg of zinc of which about 34 mg were retained Both subjects experienced an attack of chills some 10 hours later In the one case the temperature rose to 102 8° F and in the other to 101 8° F, falling again to normal within 12 hours Both subjects were under close observation in hospital during the febrile period, and a leucocytosis was observed simultaneous with the rise of temperature This leucocytosis persisted for an appreciable length of time after the body temperature reached normal Some diminution also occurred in the vital capacity Brass-founders recognise that they become more or less inured to attacks of ague, but that they lose their protection after a period away from the foundry Similar results followed inhalation of fine particles, 0 4 micron in size, of zinc oxide powder, known as Kadox, but the pyrexia was less pronounced One investigator, while making determinations as to the amount of zinc oxide present in the air of a foundry, was exposed to the fumes and experienced, as usual, an attack of ague He followed up his observations the next day, when his exposure to the fumes was even greater than on the first occasion, but escaped a second attack The other investigator submitted himself in a cabinet to zinc fumes and experienced the usual attack of fever. The next day he again subjected himself to the same exposure, but on this occasion he, too, also failed to develop an attack The writers believe that the acquired resistance is related in some way to the acquired leucocytosis which accompanies the rise of temperature and persists for some 24 hours after this has fallen The Harvard investigators denote the condition as "metal fume fever", they find that exposure to other finely divided particles, such as copper oxide and sprays of compounds of other heavy metals, such as silver, mercury, iron, and antimony, have been reported as producing the same effect They tried the matter out by exposing themselves to fumes of magnesium oxide—a product of a light metal, fever accompanied by leucocytosis followed Possibly the condition is one brought about by exposure to the inhalation of minute particles of any kind, such particles may exert a physical effect upon protoplasm, causing a disintegration which is followed by protein absorption and pyrexia, an effect counteracted by the leucocytosis The whole subject is receiving further attention at Harvard

WOLF BOYS

Since the publication of an annotation on this subject in our issue of May 7th (p 984) we have received from Dr. W. H Coupland, medical superintendent of the Royal Albert Institution for the Feebleminded, a copy of Chambers's *Edinburgh Journal* for July 17th, 1852, containing an unsigned article on an anonymous pamphlet entitled "An Account of Wolves Nurturing Children in their Dens. By an Indian Official," which was published by one Jenkin Thomas, printer, in Plymouth in that year. Reference was made in The Lancet of March 24th, 1888, to this publication, and we note that in the correspondence in the *Times* that was evoked by the appearance of the wolf boy of Allahabad Sir R. Armstrong-Jones alludes to our contribution, although he misquotes the date as 1889 In considering this "brief, rough pamphlet, published in a provincial town" in 1852, the writer in the *Edinburgh Journal* is able to recognise "both in the manner and matter the pen of Colonel Sleeman, the British resident at the court of Lucknow, whose invaluable services in putting down thuggee and dacoitee in India we have already described" Recently the correctness of this literary perspicacity was confirmed by Lieut -Colonel J L Sleeman, of Hampton House Hereford a grandsom of the famous resident, who in a letter to the *Times* of May 10th last states that the "unknown writer" of the Plymouth print was none other than his illustrious grandfather Except for the article in the *Edinburgh Journal*, ever hospitable to the unusual and the bizarre, little attention seems to have been given to General Sleeman's pamphlet, and it was not until the latter had reappeared, almost word for word, in Vol I of his "Journey through the Kingdom of Oude," published in London in 1858, that England grew aware of these Indian wolf children Serious students of philosophy then became intrigued in the subject, and grave professors of mythology and natural history endeavoured to obtain some common ground for its discussion Dr Ireland's examination and conclusion published in July, 1874, remains, however, irrefutable He studied the histories of the nine recorded cases Six of these were described by General Sleeman, first in his pamphlet and later in his book, one was under the care of Dr Whishaw, of Lucknow, as noted in our previous annotation, details of two others occur in some "Notes on Children found Living with Wolves in the North-West Province of Oude," by Mr V. Ball, of the Geological Survey of India as printed in the *Journal of the Asiatic Society* (proceedings for June 1873) Of these cases it is said "Dr Whishaw's one is of course out of the question He was neither fostered by wolves nor was he an idiot and one of Sleeman's cases is stated to have been simply rescued from wolves" All the remaining cases Dr Ireland declared to be cases of idiots "found wandering," as idiots wander in London to this day—even in London with the most watchful and the best of social services in the world

MERCUROCHROME IN THE LABORATORY.

Mercurochrome, a soluble compound of mercury with dibrom-fluorescein, has been recommended recently as an antiseptic for intravenous injection in cases of septicæmia, ulcerative endocarditis and other general infections In the belief that it confers antiseptic properties on the bile, its use has been suggested in the treatment of typhoid carriers. The bactericidal action of this drug has now been investigated[1] by L Colebrook and R Hare, both in the test-tube and the living body Whilst their experiments are neither numerous nor cover the whole area in which bactericidal action might be manifested, they nevertheless should suffice to indicate any striking value possessed by the preparation In brief, their findings have been that mercurochrome, added to human defibrinated blood outside the body, in no way enhances the bactericidal power of the blood, that the intravenous injection of the drug does not increase the bactericidal action of the blood when tested shortly afterwards, and that no special antiseptic properties are conferred upon the bile by such an injection These results are of some importance, and should engage the attention of those who counsel the use of mercurochrome Whilst they are open not only to the objection of their scantiness, but also to the common criticism which may be levelled against this class of experiment in general—that it does not throw direct light upon the actual processes within the body—they certainly fail to indicate any antiseptic action of the drug within their obvious limits The fact that good clinical results have been recorded in cases of severe septic infection is possibly to be explained as a result akin to those obtained with eusol, with the non-specific intravenous injection of vaccines, and with the intravenous injection of other substances of high molecular weight These results are probably non-specific and due to the implication of some mechanism at present little understood

TREATMENT OF SNAKE-BITE.

Practically every part of the United States is inhabited by poisonous snakes, and in certain regions large projects for agricultural development are held back through the immigrants' fear of this peril New agricultural development means an increase in rodents and small animals which form the staple diet of the snake, and the hazards of farming in the tropics are very real Snake-bite therefore constitutes a distinct problem in public health, and the Mulford Biological Laboratories, of Glenolden, Pa, include an Antivenin Institute for the purpose of furthering knowledge of all animals poisonous to man and of developing means to prevent death and alleviate symptoms due to their attack This institute has just brought out its first *Bulletin*, which is to be a quarterly publication dealing with all the ramifications of snake-bite and kindred problems The editors aim at making it an authoritative source of information and a medium of popular education The issue opens with an article by Mr Raymond L Ditmars on the occurrence and habits of poisonous snakes The author acquits Maine and New Hampshire of the charge of harbouring these pests, but cannot altogether clear Vermont, as rattlesnakes are occasionally reported from there Rattlers extend well over the rest of the States, and the swampy southern districts are overrun by many other species It appears that copperhead snakes still exist within the actual boundaries of New York City and in many other eastern towns they are living very close to Main Street The writer describes more than a dozen kinds of rattler, as well as the copperhead, moccassin, and coral snakes The majority of northern snakes are well disposed and will not strike if unmolested, to their retiring habits alone does Mr Ditmars ascribe the rarity of bites among the silk-stockinged low-shoed "hikers" from the towns Snakes seem to dislike modern motor roads and are confined to the areas included by the highways In the south matters are very different Rattlers prowl over open areas of country and flash instantly into a fight instead of seeking a friendly crevice, an envenomed blow is driven before the intruder is aware of the enemy's presence Leather gaiters from knee to shoe give 90 per cent protection Mr L M Klauber gives more detailed descriptions of the south-western species of Crotalus, and maintains that in his district very few snakes will fight without considerable provocation His article is illustrated by photographs which should materially help in identifying the different reptiles Mr M L Crimmins contributes a note on Texas rattlers and describes the symptoms of a bite, which are primarily hæmolytic and secondarily neurotoxic Blood cells and other tissues are destroyed and gangrene is likely to follow a bite The San Antonio station recommends prompt application of a tourniquet, loosened for five seconds every 20 minutes to prevent gangrene, a cross-incision one-third of an inch deep, and soaking with 1/3000 permanganate The usual first-aid treatment is kerosene oil, and the 19 cases subsequently treated with serum were nearly all a day old and suffering from very grave symptoms Yet all recovered It seems therefore that anticrotalic serum is a valuable addition to the pharmacopœia of agricultural doctors in the States, and it is a pity that it is at present so rare that it can only be used to prevent death in grave cases and not to relieve suffering in milder ones Other more technical papers in this interesting *Bulletin* include studies of neotropical and African snakes by Messrs T Barbour and A. do Amaral We have in Great Britain no rattlesnake problem, but our native venomous reptile, the viper, is responsible now and then for a case of severe illness, more often still for much pain and alarm, and the rarity of its attack is no reason for ignoring the problem Where distances are so small it ought to be possible for some central laboratory to keep a stock of antiviper serum ready for use Its director at any rate will not have to emulate Major Scott, of the Fort Sam Houston Laboratories, who flew 2600 miles to administer antirattler serum in Texas

THE SIZE OF THE THYMUS

Evidence continues to accumulate that the discovery of a large thymus and ample lymphoid tissue elsewhere in the body does not satisfactorily explain an unexpected death in an apparently healthy child Dr Edith Boyd, in a communication to the Minnesota Pathological Society,[1] concluded from her studies that the "status thymico-lymphaticus" represents the normal thymus and lymphoid tissue of a well-nourished child This is in effect the same as the provisional verdict[2] of the joint committee appointed by the Pathological Society and the Medical Research Council to look into the matter, and we await the further and final findings of that committee with interest Ignorance of the normal body is a serious defect in all studies in morbid anatomy, in this particular instance it has naturally been rather difficult to believe that a few days fever or digestive disturbance or, indeed, illness of any kind, will cause such a marked wasting of the lymphoid tissue throughout the body that our conceptions derived from the average hospital case are quantitatively all wrong But there seems little doubt that this is actually the case, and the pathologist will have to look further than the thymus for the explanation of some of the tragedies which he is called upon to elucidate It seems that a large or abnormally persistent thymus is significant mostly in endocrine disorders which commonly fall on adolescents and young adults In exophthalmic goitre a persistent thymus is almost the rule, especially in young subjects, which corresponds with the experimental observation that removal of the thyroid hastens the natural involution of the thymus This is retarded by adrenalectomy, which may bring about actual regeneration, as is shown in a certain number of examples of Addison's disease Apart from such relationships considerable caution is necessary in charging the thymus with any primary vice of being too big

RISKS OF CHILDBIRTH IN VICTORIA.

The incidence of maternal mortality and morbidity has in recent years engaged the attention of the medical profession in Australia, as in other English-speaking countries Some time ago the University of Melbourne appointed Dr. R Marshall Allan as director of obstetric research for two years, "to inquire into the causes of maternal mortality and morbidity in Victoria, and suggest means to prevent or lessen the same" Dr Allan's interim report, which has now been issued, is based upon an inquiry which included (1) a statistical investigation, (2) an exhaustive study of domestic obstetric practice, involving personal interviews with medical practitioners and the inspection of all hospitals registered to admit obstetric cases, (3) clinical research. On a total of 35,922 births, the maternal mortality-rate in Victoria for the year 1925 was 4 3 per 1000 live births The decrease in deaths from all puerperal causes since 1905 is 23 per cent, and in the death-rate from sepsis of 38 per cent, though sepsis is still responsible for slightly more than one-third of all puerperal deaths Notification, to be of any use, must be carried out with knowledge and intelligence In Victoria it is so little understood that more than once in the years 1921–25 the deaths from puerperal fever exceeded the total notifications. Dr Allan sees great danger in this tendency to "shelter behind a fictitiously low mortality-rate," and says that "the first result of an awakened professional conscience will be an increase in the number of deaths reg stered, and a rise in the statistical rate due entirely to more accurate certification of the cause of death" He points out that statistics on a small scale may lead to erroneous conceptions, and that Victoria's task is not to compare her situation with standards of other countries, but rather to face the fact that she is losing 150 mothers a year from causes connected with childbirth, a loss which cannot be afforded, and to determine that dissatisfaction shall be the prelude to such cooperation between the public and the medical profession as will lead to prevention.

Obstetric nurses in Victoria are not controlled by the General Nurses' Registration Board, but by a separate Midwives' Board composed of five public service members, "none of whom are in touch with current obstetric problems" The Board of Examiners, however, consists of three doctors and a nurse, all in active practice, and Dr Allan speaks appreciatively of the way in which examinations are conducted, though he considers that the written and oral tests should be supplemented by a practical examination at the bedside There are at present 2646 registered midwives, of whom half are trained, the other half being permitted to "practice" on the basis of previous experience Difficulty is experienced in persuading the well-trained woman to take up obstetric practice, largely owing to the influence of untrained nurses who are prepared to combine domestic duties with their nursing care About 60 per cent of all confinements in Victoria take place in either public or private hospitals Hitherto private hospitals have been allowed to register as training schools, but, on the advice of the Board of Examiners, the Midwives' Board has refused to register any more Good obstetric work is carried out at the Women's Hospital, Melbourne, The Queen Victoria Hospital, and at the St George's and Bethesda "intermediate" hospitals, the two latter having had one death among 400 patients and two deaths among 1317 patients respectively

[2] Jour Path Bact, 1925, xxviii, 132

Dr Allan deals sympathetically with the difficulties which face the conscientious obstetric practitioner in the suburbs of Melbourne, and which differ in degree but not in kind from those met with in this country Patients and their relatives, often backed up by ignorant nurses, clamour for anæsthesia and quick delivery, hospital accommodation is poor and the nurses are untrained, while the desire to take the maximum number of cases is a temptation to hurry delivery Dr Allan had personal interviews with 230 practitioners, and he pays a high tribute to many "faithful disciples of the obstetric art" in the smaller townships, who manage to maintain a high standard of efficiency under discouraging circumstances He recommends the establishment of large modern maternity units with accommodation at reasonable rates Among some practitioners a tendency was noted to resort too easily to operation for contracted pelvis, and to make too frequent vaginal examinations Out of 132 cases of Cæsarean section the majority were performed for contracted pelvis, placenta prævia, and toxæmia, and the mortality following this method of treating eclampsia and placenta prævia did not compare favourably with that following more conservative methods There is still hard work to be done in educating the public, and providing conditions in which practitioners can do their best work, but Dr Allan is convinced that the majority at least are on the right road

NATURAL HEALING IN PULMONARY TUBERCULOSIS.

ALL through the nineteenth century pathologists exercised their minds with the question What are the true characteristics of the histological lesion of the tubercle, especially as it affects the lung? Even the discovery of the bacillus did not finally settle the question, though it narrowed it down to limits within which reasonable discussion could take place and emphasised the ætiological unity of all the lesions of pulmonary tuberculosis The names of those who have entered upon this, now classical, discussion are legion In a recent monograph, Dr Marc Jaquerod[1] has essayed to carry the subject a stage further by defining the natural processes of healing which occur in pulmonary tuberculosis He starts out from the standpoint of Letulle and Bezançon that the two essential lesions of the disease are (1) an "inflammatory nodule of the connective tissue constituted by a coalescence of a variable number of primitive giant-celled follicles," and (2) a "bacillary broncho-alveolitis"—which correspond respectively with the productive and exudative lesions of the German pathologists, but he considers that the three well-recognised morbid anatomical results of inflammation described by pathologists—viz, caseous degeneration, fibrous transformation, and calcification—are not all There may be a fourth process, resolution, which escapes the eye of those who make post-mortem examinations In proof of this the author quotes the example of a fresh laparotomy, performed years after a previous one, when the tubercles seen on the first occasion were found to have disappeared without a cicatrised vestige of the disease "But mention these facts," he adds, "to a pathologist, who is not also a clinician, and he will deny them Why? Because he has not seen them" Dr Jaquerod believes that the reabsorption of bacilli and inflammatory products, *probably* by a humoral process rather than a phagocytic one, is possible Bacteriolysis indeed, may promote resolution whilst phagocytosis may produce metastases by transporting bacilli to a distant part of the body, a point strongly emphasised also by Calmette In other words, given adequate rest and time for the humoral process to act, a lesion may clear up little by little and end by being completely cured The monograph contains many beautiful radiograms illustrating clinical points in the argument, with chest diagrams of physical signs accompanying them—a wholly commendable method of demonstration—but the pathological evidence for the thesis of complete resolution of the lesions of pulmonary tuberculosis is entirely lacking The pathologist is in fact warned off the field of discussion early in the book by the time-honoured test of agnosticism that those who cannot see will not believe By analogy with other diseases of an infective nature, resolution in tuberculosis is obviously not impossible; but without adhering to the old adage "once tuberculous, always tuberculous" we believe pathological proof of resolution should be forthcoming if it is really a fact The evidence of the radiogram cannot be taken as final

The Services.

Surgeon Rear-Admiral Arthur Gaskell, C B, O B E., takes up the post of Director-General of the Medical Department of the Navy, in succession to Surgeon Vice-Admiral Sir Joseph Chambers, K C B, C M G, on July 1st

ROYAL NAVAL MEDICAL SERVICE

Surg Rear Admiral J F Hall is placed on the Retd List at his own request

Surg Lt (D) C Williams to *Vivid*, for R N Barracks, Devonport, for duty at St Budeaux

ROYAL NAVAL VOLUNTEER RESERVE

Surg Sub-Lt H M Willoughby to be Surg Lt

WAR OFFICE

Col J P Helliwell, late the A D Corps, from Inspr of Dental Servs, to be Asst Dir-Gen (for the Dental Servs)

ROYAL ARMY MEDICAL CORPS

Capt W Bruce to be Maj
Capt C F Anthonisz to be Maj (Prov)
E M Wright to be Temp Lt

ROYAL AIR FORCE

Flight Lt C G J Nicolls is granted a permanent commission in this rank

Flying Officer P D Barling is promoted to the rank of Flight Lt

DEATHS IN THE SERVICES

Surgeon-General Henry Cook, I.M S (retired), died at Lee-on-Solent in his ninety-sixth year on May 30th. He studied medicine at St George's and St Mary's Hospitals and qualified with the M R C S Eng. in 1854 After joining the Indian Medical Service, he served with the Persian Expedition of 1857, and with the Abyssinian Expedition of 1867-68, receiving medals on both occasions He had been principal and professor of medicine and hygiene at Grant Medical College, Bombay, and Dean of the Faculty of Medicine at Bombay University Surgeon-General Cook was a Fellow of the Royal College of Physicians of London, of the Royal Geographical Society, of the Royal Microscopical Society, and of the Geological Society, and a justice of the peace for Gloucestershire

---

DOCTORS AND SICKNESS BENEFIT —At the annual congress of the National Deposit Friendly Society on *May 28th* Mr F Acton, the President, drew attention to the fact that in panel practice a medical man who refuses to grant a sickness certificate is liable to lose his patient. Some measure ought to be devised by the Ministry of Health, he said, which would qualify or check the right of the patient to go to another doctor

IMPORTATION OF DRUGS —The Board of Trade intends to exempt uncompounded drugs from the requirement that imported goods bearing a British name or *trade mark* must also bear an indication of origin *This* exemption will not extend to proprietary articles, or to articles sold in their original packing Communications on the subject should be addressed before June 7th to the Secretary, Board of Trade, Great George street, Westminster, S W 1

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXXVI

CHRONIC GONORRHŒA IN WOMEN

Chronic gonorrhœa in women is one of the most difficult diseases to cure completely, The patient may have had a discharge for some years which she has neglected, through ignorance of its significance, or she may have had an attack of acute gonorrhœa and abandoned treatment too early In any case, the practitioner usually has the condition brought to his notice through some other illness, which when traced to its origin, reveals an old gonococcal infection as the primary source The superimposed illness may be an arthritis of one or more joints, the joints most frequently affected being elbow, wrist, finger-joints, knee and ankle. When other possible foci of infection, oral or intestinal, have been excluded, a patient may be found to have a discharge which, she says, is of long-standing, and causes her no trouble Again, the patient's symptoms may be purely pelvic, she may complain of menorrhagia, of pain in one or both iliac fossæ, or of sacral backache, but will stoutly deny that she has a discharge. The persistent practitioner will frequently find evidence of old-standing infection on pelvic examination, and such an examination should become recognised as an essential part of a general overhaul Sometimes also after patient investigation a suggestive previous history is obtained—an attack of severe cystitis some time before, or a baby with ophthalmia neonatorum There may be a history of pyrexia after an easy childbirth, followed by a considerable period of pelvic illness with menorrhagia, and even sometimes metrorrhagia, finally there remains a vaginal discharge, mostly slight, which causes little inconvenience. In many cases, on examination, old patches of staining will be seen round urethral or Bartholin orifices, and by massage of the anterior vaginal wall gleet or muco-pus can be expressed from the urethra Vaginal examination will almost certainly reveal a chronic cervicitis, with an erosion and muco-purulent exudate, and often thickening of the Fallopian tubes The discharge will contain mainly secondary organisms Gonococci are rarely found in such cases unless from a urethral film The gonococcus is, of course, intracellular at this stage, within polymorph or epithelial cells, therefore douching or painting alone cannot eradicate the disease The complement-deviation test for gonorrhœa is of doubtful value in the chronic stage, while cultures mostly grow only staphylococci

The practitioner may know well that the disease is a chronic gonorrhœa, but he should be chary of making his diagnosis known to the patient or her husband unless the previous attack of gonorrhœa is admitted or the gonococcus has been definitely isolated. The diagnosis may well be left at "chronic urethritis or cervicitis," but the importance of the lesion and of the discharge as a focus of infection must be stressed Many puerperal septicæmias are undoubtedly due to a chronic gonorrhœa

Local Measures.

Treatment must consist primarily in keeping the patient clean and comfortable, by clearing away obvious discharge by careful douching, at the same time taking care to avoid over-douching The douche material used depends on the type of discharge and on the practitioner's own preference

Patients left to themselves frequently choose lysol douches and these, if not thoroughly mixed, or if used too strong, seem to make her more sore and less confortable than before My preference in very purulent cases is for a douche of 1 per cent lactic acid, or of sanitas, or of liq sodæ chlorinatæ 1 in 80, or weak pot permang In less purulent cases a plain douche of hypertonic saline, or of boracic, or of zinc-alum powder in equal parts, ℈1 of powder to each pint of douche water, is useful and comfortable Bladder and urethral washouts must, of course, be done with bland, non-irritating drugs I use 1 in 8000 permanganate solution or boracic ℈ 1 to pint, or 1 in 6000 biniodide of mercury, taking care that none of the biniodide solution remains in the bladder

The accepted drug for application to the cervix in gonorrhœa has for long been one of the preparations of silver. but though these salts have a wide field of usefulness, I do not use them exclusively Saturated solution of pot permang, 20 per cent mercurochrome, and 1 in 100 acriflavine are among other useful drugs An important point to remember when painting the cervix is that any adherent mucopus must be dissolved with liq potassæ, or better still, with a saturated solution of sodii bicarb before the antiseptic paint is applied In painting erosions of cervix, a solution of picric acid is sometimes useful, or 10 or 15 per cent picric in alcohol may be employed No useful purpose is served, however, by undue use of caustic substances in painting the cervix Soluble pessaries of contramine, lactic acid, or of ordinary sulphur or of protargol are sometimes placed against the cervix, and kept in position by a dry tampon which is removed 12 hours later, or tampons soaked in one of the glycerine preparations may be preferred—e g, glyc boracis, glyc ac tannic, or glyc with 5 per cent ichthyol and 2 per cent lactic acid This last is a most useful tampon, though in some patients if it is continued for more than a few days an irritant vaginitis results Small lesions such as Nabothian cysts on the cervix must be punctured, Skene's ducts and ducts of glands of Bartholin, if infected, must be washed out with an antiseptic solution twice or three times a week

This treatment is only satisfactory when carried out by a well-trained gynæcological nurse, or by the doctor himself Self-douching by the patient is useless; a good nurse will accomplish in three weeks what it will take the patient three months to achieve

In addition to local applications measures directed towards raising the patient's resistance are required if the disease is to be eradicated

Vaccines

Vaccines have had periods of disrepute To get a really good result from their administration, it is necessary to have a vaccine freshly made from organisms of a vigorous strain The vaccine may either be autogenous or stock If a stock vaccine is used it must come fresh from a reliable source otherwise both practitioner and patient will be disappointed with the result

The best vaccine for a chronic gonorrhœa contains gonococci and secondary organisms combined, the usual mixed vaccine consisting of gonococci, staphylococci, streptococci, and diphtheroid bacilli The first dose for a woman in average health should be from 25–40 millions, depending on her body weight After a week, if the patient has not had a reaction the dose may be doubled A reaction is indicated by rise of temperature and pulse-rate from 6–24 hours after the injection, by headache sickness, or backache, or by a general feeling of malaise Should there have been a slight reaction only, an addition of 50 per cent to the previous dose may be given a week later When a really marked reaction occurs the dose should be repeated at the next injection, instead of being increased The injections are best given at intervals of a week to begin with, and later at intervals of 10–14 days Too frequent doses seem to induce a negative phase and to retard recovery

After eight to ten doses of vaccine, even if the patient has improved, there should be a rest of a couple of months; then another series of vaccines or another method of accessory treatment may be begun

Non-specific Protein Therapy

"Non-specific protein therapy" has many advocates at the present time, and has proved of great use It is simple and inexpensive, a drawback is the considerable reaction—local or general—so that the patient has to be prepared to lie up, or at least "go slow," for 24 hours after an injection

For housewife or business woman alike, an injection on a Saturday afternoon is convenient, the patient arranging to be in bed not later than four or five hours afterwards The reaction usually begins with rise of temperature and pulse-rate, the maximum rise—which may be 102° F—occurring 8–12 hours after injection During this period, naturally, the patient feels far from well, and usually aches all over Some patients experience no general reaction, but complain of very severe pain and stiffness at the site of injection The injections should be intramuscular, the gluteal muscles being generally chosen in women. It is best for the patient to have no other drug, but should the reaction be too severe, 10 gr of aspirin will make her comfortable

Before starting protein injections it is wise to make sure that the patient is not subject to asthma or hay-fever Such patients tend, a few seconds or minutes after injection to have a marked vasomotor reaction, with severe flushing of face and neck, suffusion of conjunctivæ, very rapid pulse and a feeling of suffocation, or as if the head would burst. Administration of hypodermic injection of 10 minims of adrenalin (1 in 1000) P.D & Co, usually clears this at once, but if it does not do so completely, the dose can be repeated in 10 minutes Such reactions are rare

There is usually an exacerbation of the discharge for 24 hours after the injection, followed by improvement. A marked leucocytosis while the reaction is at its height gradually subsides till, in a few days, the white count is practically normal. These injections may be repeated weekly, four are usually enough. The materials most frequently used are milk, a collosal silver preparation, or T.A.B or some similar vaccine Milk is prepared by standing it in a boiling water-jacket for 10–15 minutes A clean, boiled test-tube can be three-parts filled with milk, stopped with flamed cotton-wool in the usual way, and stood in a steriliser or small enamelled basin of water which is then brought to the boil and boiled for at least 10 minutes The doses of milk usually given are 4, 5, 8, and 10 c cm in successive weeks

Sometimes *B. coli* vaccine is given at the same time as the milk injection; or a dose of electrargol (collosal silver) may be given intravenously, followed immediately by a small hypodermic dose of mixed gonococcal vaccine Sometimes T.A.B is given weekly in doses of ½ to 1 c cm till three or four doses have been given The underlying idea of all these injections is the same

The Glycerine Drain

In a chronic gonococcal endometritis with discharge and menorrhagia, great relief is often obtained by using the glycerine drain

This simple method was introduced by Dr Remington Hobbs, and as usually practised consists in gentle dilatation the cervix to No 7 or 8 Hegar About 2 c.cm. of pure glycerine is then injected into the cavity of the uterus from a sterile 5 c.cm. syringe, a small rubber drainage-tube is inserted through the internal os and is left to drain into the vagina, which is lightly packed with iodoform gauze, the gauze is removed in 24 hours, the rubber drain 24 hours later In a multipara an anæsthetic may not be required, only a very short anæsthetic is required in any patient, and the patient is in no way upset by the manipulation

This method has usually to be repeated, in a chronic case two or three times, at intervals of three weeks or so Some gynæcologists prefer to pack the uterine cavity with 50 per cent glycerine and iodine, or with 5 per cent mercurochrome in glycerine

Diathermy.

Where there is a chronic urethritis of some duration, in my opinion there is no treatment so effective as diathermy, as suggested and practised by E. P. Cumberbatch and J. W. Arthur Robinson.

By means of a diathermy machine with special electrodes a temperature of 112° F in the patient's urethra can be reached and maintained for 10 to 15 minutes without causing pain, and most obstinate cases of urethritis have been completely cleared up Similarly, in cases of chronic cervicitis, a heat of 112 5° to 113° F can be safely borne by the cervix for 10 to 15 minutes, a cervical electrode, shaped like a uterine sound but containing a thermometer is used This penetrating heat is highly inhibitory to the gonococcus, and the patient has no discomfort, but rash applications of 115° to 120° F invariably produce pain, from pelvic congestion, which may persist for a couple of weeks This treatment gives admirable results in cases of gonococcal arthritis, the joints clearing up sometimes as if by magic. Before administering diathermy treatment the practitioner must have careful tuition, since inexpert handling will inevitably produce pain or even severe burns

One last word; if a married woman has a chronic gonorrhœa, time, patience, and money are thrown away on treating her if her husband has old untreated prostatitis or vesiculitis

MARGARET RORKE, M B, Ch B Glasg,
Medical Officer in Charge of the Female V D Department,
Royal Free Hospital.

GENERAL MEDICAL COUNCIL.

SUMMER SESSION, 1927

TUESDAY MAY 24TH

PENAL CASES

In accordance with the usual custom the penal cases were heard in public, the Council deliberated on them in camera and the results were then announced

The Registrar read the report of the Dental Board in regard to Joseph Halliday Magee, registered on Dec 7th 1922 as of 53, St. Mary's-terrace, Tyne Dock 'Dentist 1921'; charged with canvassing for patients on board certain ships On hearing the statement of Mr. Magee, the Council decided to remit his case to the Dental Board for further inquiry.

Another report from the Dental Board charged Samuel Theodore Hilton, registered on Nov 29th, 1922, as of 16 East-crescent, Manton, Worksop, 'Dentist 1921." with canvassing Mr Hilton did not appear The Council ordered that his name be erased from the Dentists' Register

The Case of Samuel Grahame Connor registered as of 119, Oxford-street, London, W. 1, M.B, C.M. 1889. U Edin Dr Connor had been charged before the Council at its Summer Session, 1926, with having been convicted at Marlborough-street police-court on three summonses for an offence against the Dangerous Drugs Act and the Council had postponed judgment for one year, directing him to produce evidence of his good professional behaviour during the interval[1] On considering several testimonials and hearing the assurance of Dr Connor that he would take care never to lay himself open to such charges again, the Council did not see fit to erase his name from the Register.

The Case of Austin Heron registered as of the West African Medical Staff L. L.M. 1924, R.C.P. Irel., L., L M 1924, R C S Irel. Dr. Heron had been charged before the Council on May 29th 1925, with having been convicted for obscenely exposing his person to certain females, and judgment had been postponed for a year. In 1926, Dr Heron being absent on service judgment had been postponed for a further year. On considering his testimonials and his personal assurance of his intention to maintain good professional behaviour the Council decided not to erase his name from the Register.

The Case of Jogesh Chandra Bose, registered as of 276 Cherrywood-road, Birmingham, M.R C.S, L R.C.P. 1923 The charge against this practitioner was as follows:—

That, being a registered medical practitioner, you on Feb 1st, 1927, signed and issued the following certificate, viz. —

> This is to certify that William Hopkins, residing at 5/149, Fazeley-street, is suffering from bronchitis and is not able to attend school.
> 1.2 27 J C BOSE, M R C.S;

whereas the said William Hopkins had not been under your medical care, nor had you seen or examined him on Feb 1st, 1927, or at all, which certificate was untrue, misleading, or improper; and that in relation thereto you have been guilty of infamous conduct in a professional respect

The complainants the City of Birmingham Education Committee, were represented by Mr. Digby Seymour solicitor. The respondent was represented by Mr. Oswald Hempson, solicitor

Mr John Stevenson, chief superintendent of the Birmingham School Attendance Officers, speaking to his statutory declaration stated that respondent had admitted in his presence having written the certificate in answer to a request from the mother, Florence Hopkins, transmitted through her small daughter on Feb 1st Respondent had written a letter on Feb 27th to Dr. Innes the chief medical officer of schools, in which he had admitted not having examined the boy and expressed regret On Feb 7th the Education Committee had received a letter from Mrs Hopkins explaining that she had not asked Dr Bose to examine the boy because she had not had the money, but had thought it would be unnecessary because the doctor had been visiting every week, and knew her complaint (the message had been "Mother has 'flu and thinks Willy has got it too")

---

[1] THE LANCET, 1926, i, 1147

Mr Thomas Alan Jinks, divisional superintendent of the Birmingham School Attendance Officers, corroborated The documents were put before the Council

Mrs *Florence May Hopkins, mother of the boy* William, stated to her statutory declaration that the boy had not been attended by any doctor He had been absent from school for a week from Jan 30th On Feb 1st she had sent her daughter Vera to tell Dr Bose that she (witness) had influenza, and that she wanted a second note for William Dr Bose had sent her a prescription, and a certificate stating that William was suffering from bronchitis She had sent the certificate to his school, and paid Dr Bose 6*d* for it She had really wanted her son to stay at home and look after the children On Feb 5th, witness stated, Dr Bose had visited her and said that there had been trouble about the certificate, and had offered her 5*s* to say nothing about it She had refused to take this, but he had put it on the dresser On the 12th Dr Bose had come again, saying that he was going up to see the school medical officer, and asking her if she had heard any more about the matter On the 19th he had brought her a £1 note and asked her again if she had heard any more, he had given her another 5*s* on leaving He had promised her £50 to say nothing On the 25th she had written to him asking for a loan of £2 and on the 26th he had come to the door and handed her two 10*s* notes Cross-examined, however, she admitted that she had received two letters from Mr Bose's solicitors, denying any liability and threatening action if she asked him for any more money, and made any further derogatory statements about him She admitted having written to Mr Bose charging him with indecent intent in asking her on one occasion to speak to him upstairs, although relatives had been present on that occasion She admitted having said nothing about these matters in her statutory declaration

Richard George Hopkins, nephew of Florence Hopkins, corroborated her evidence regarding the gifts of money Under cross-examination he fainted, and no further questions were asked

William Hopkins also gave evidence corroborating his mother's

Mr Bose, giving evidence in his own defence, admitted having written the certificate without examining the boy William, but stated the he had seen him three days before, and that he had then had a cold and a cough He expressed his regret, and an undertaking that he would be more careful in future He denied ever having given Mrs Hopkins any money to keep silent, but stated that she had attempted to blackmail him, by threatening to inform the medical officer of schools She had written him two letters, which he had referred to his solicitors, who had replied suitably. Her charges against him of bribery and of making an indecent suggestion had been brought to protect herself from the accusation of blackmail

Mr Bose's adviser put in several letters testifying to the respondent's excellent character and conduct

The President announcing the decision of the Council, said that it had been proved to their satisfaction that the certificate in question had been given in a lax and careless manner, and was in fact untrue, misleading, or improper The Council regarded laxity in the giving of certificates as a grave matter, likely to result in injurious consequences to patients and others, and worthy of severe censure In order, however to give respondent time to reconsider his position in this regard, they had decided to postpone judgment until the November session of this year. Respondent would be required before that date to supply the names of two or three professional brethren who would be prepared to testify to his character and conduct in the interval

WEDNESDAY, MAY 25TH

The Case of Frederick Joseph William Porter, D S O registered as of the Army Medical Service, L S A Lond, 1889, M R C S Eng, L R C P Lond, 1890 The charge against this respondent was that he had sought to obtain patients, and promote his own professional advantage, by means of notices inserted in the Indian press The notices read —

1 In the *Times of India* of Feb 5th, 1926 "Major F J W Porter, R A M C, D S O, has now returned to India from England after an absence of a year, and will shortly resume his practice at Karachi" 2 In the *Kaisar-i Hind*, Bombay, of Feb 7th, 1926 "Major F J W Porter, R A M C, D S O, has now returned to India after a year's absence in England and will shortly take up the practice in Karachi"—(*translation*) 3 In the *Daily Gazette* of Feb 8th, 1926 "Major F J W Porter, D S O, R A M C, has now returned to India from England after an absence of a year, and is putting up at the Carlton Hotel, where he may be consulted" 4 In the *Sind Observer*, Karachi, of Feb 8th, 1926 "Major F J W Porter, D S O, R A M C, who was formerly in Bombay, has now returned to India after an absence of a year and is putting up at the Carlton Hotel in this city, where he may be consulted" 5 In the *Parsi Sansar*, Karachi, of Feb 10th, 1926 "Well-known surgeon in Karachi Major Porter, the well-known surgeon of Bombay, has returned to India after a year's absence in England, and is staying at the Carlton Hotel, where he may be consulted"—(*translation*) 6 In the *Sindvasi*, of Hyderabad, Sind, of Feb 17th, 1926 "Major Porter in Karachi The people of the *Times of India*, Bombay, write that Major Porter, D S O and R A M C, retired, has come back to India after an absence of one year, and stays in the Carlton Hotel, Karachi, where he can be consulted"—(*translation*)

The complainants who did not appear, were Lieut -Colonel Ivor Davenport Jones, I M S, M B, Major Charles Newton-Davis, *M C*, I M S, M R C S, and Dr Guy Theodore Wrench

The respondent was accompanied by Mr Oswald Hempson, solicitor In answer to the charges, he stated that until April, 1923, he had practised in Bombay, and that he had then retired to England, but had been compelled to return to Bombay and start practice afresh In 1924 he had again tried to retire, but had had to go back a second time in 1926. In 1923, when he had arrived in Bombay, he had consulted the Registrar of the Bombay Medical Council, giving him the form of the proposed announcement, and had been told that he might insert it at least twice. The form stated that he had arrived and was staying at a certain address When he returned in 1926 he had been advised to go and practise in Karachi Since he knew one of the directors of the *Times of India*, he had asked him to put in announcement (1), and his friend had done so He had not seen the necessity for consulting the Registrar again, as this was practically the same announcement that he had had inserted in 1923 It had appeared in the social and personal columns, items in which were never paid for At his request, the *Times of India* had sent the announcement to the Parsee journal, *Kaisar-i-Hind* He had gone personally to the editors of the other papers and given them copies of announcement (1) He had inserted the phrase, "where he may now be consulted," in order to avoid being mistaken for a "globe-trotter" He had not instructed them to vary the notice, and had not seen the translations until they had appeared, when he had been disgusted He had obtained a statement from the editor of the Parsee journal that the announcement had not been given him in the words that were printed The complainant, Dr Wrench, had, because of these announcements, refused to make his acquaintance, and had made defamatory statements about him to other people In April, 1926, respondent had commenced an action against Dr Wrench in the local police-court, since the Bombay registrar had informed him that his conduct was covered by

Rule 23. This was a criminal action but civil process took an impracticably long time. The magistrate had dismissed his summons Cross-examined, he *admitted that he had known that the Indian Penal* Code provided a penalty of two years' imprisonment for defamation of character, also that he had failed in a similar action several years before.

The Council found the facts alleged against the respondent to have been proved, but postponed judgment, subject to the usual provisions, until the May session of 1928.

The Case of John Morrison Lever registered as of 6 Savile-road, Chapeltown Leeds L M.S S.A Lond, 1917, M B, Ch.B, 1917, Univ Leeds This practitioner was charged with knowingly enabling by his countenance or assistance, women not certified under *the Midwives Act, 1902, to attend certain women in* childbirth, under cover or pretence that the patients were attended, or to be attended by the uncertified women under his direction and that in each case he signed a maternity benefit certificate, thereby enabling the uncertified women, in contravention of the said Act, to practise as if they were certified thereunder. The complainants, the London County Council were represented by Mr Pawlyn, assistant solicitor to the L C C Dr Lever was accompanied by Mr. Charles Davis, of Messrs Bulcraig and Davis, solicitors

Mr. Pawlyn stated that, with *one exception*, the women concerned had refused either to make a sworn declaration or to attend before the Council to give evidence Mr. Davis objected to the sworn declaration of Albert Garner, an inspector of the Public Health Department of the L C C, on the ground that it contained hearsay evidence, and the Council, advised by its legal assessor, decided to admit only such parts of this declaration as the witness could testify to from his *own* knowledge.

Mr Garner, in evidence, stated that during the early part of 1926 he had been engaged in making inquiries into the practices of the unregistered women mentioned in the charge. He had been present at the proceedings against one of them, Mrs Ketley, before a magistrate, when she had been bound over for a year He had seen all the women *concerned* in the present charge but had failed to induce any of them, except one of the mothers to make a declaration He identified the maternity benefit certificates signed by respondent in favour of the mothers in the case He had not asked Dr. Lever to appear at the proceedings against Ketley, nor told him that they were being instituted

Mr Pawlyn put into court the declaration of Mrs Rose Baldwin, in which the deponent *had stated that* she had engaged Mrs Ketley to attend her in her confinement for 15s. She had informed Dr Lever of this The birth *had taken* place at 2 30 A.M., and respondent had examined her on the following day, but had not been present at the actual birth He had attended her for some time afterwards, and had signed the maternity benefit.

Dr Lever's adviser submitted that there was no case for the respondent to answer and placed him in the witness-box to explain the circumstances

Dr. Lever stated that Mrs Baldwin's husband had called on him one morning saying that his wife had been confined during the night, and that the local doctor she had engaged had *refused to attend* her Respondent had attended her for the remainder of the time that she had been in bed He had visited her as soon as he could after her husband had called him in He had made no arrangement of any sort or kind with Mrs Ketley He produced his day-book in evidence of the fact that he had been engaged by all the other women before their *confinements* and had actually visited them before and after the births Cross-examined, he denied any cooperation of any kind with the uncertified women in his district The mothers used to engage them months ahead and the fees of the certified women, none of whom lived very near, were beyond their means

On a motion of Mr H L Eason, seconded by Sir Robert Bolam, the Council resolved to deliberate on the case without hearing any further evidence As a result of their deliberation they decided that the *charge had not been proved, and dismissed the case*

FRIDAY, MAY 27TH

The Cases of Lawrence Crombie registered as of Dunollie, Dalmuir, Glasgow, M B, Ch.B, 1913, Glasg.; of *Eliazer Gelfer*, registered as of 45, Abbotsford-place, Glasgow, C 5 L R C.P, L R.C S L.R F.P S., 1923, and of *William Mason Hamilton* registered as of Law Junction, Lanarkshire, M.B, Ch.B, 1921, Glas.

These practitioners had been summoned to appear before the Council on the charge of employing under cover of their own *qualifications*, assistants who were left in charge of premises where scheduled poisons were sold to the public, but who were not legally qualified to sell scheduled poisons

The complainants were the Pharmaceutical Society of Great Britain. Mr. O. Hempson accompanied Drs Crombie and Hamilton Dr Gelfer was not present but sent his defence in writing

Dr Gelfer, in his letter, stated that the poison which his assistant had sold was a 4-oz. bottle of lysol, sealed and labelled as poison with instructions for use He had never heard that any qualification was needed for its sale He had stopped the sale of lysol three months ago, when the inspector, who had been the first to ask for a bottle, pointed out his misdemeanour The lysol had been for his own and his wife s use. He did not employ his assistant to sell scheduled poisons, and all except the lysol were kept locked up

Dr Crombie stated in evidence that his assistant had sold some Jeyes' fluid without his knowledge She had been told she must not sell poisons He had a qualified chemist to run his dispensary He had now removed his poisonous disinfectants Cross-examined, he said that the Jeyes' fluid had got loose into the cupboard from his surgery by accident. He did not know how it had been sold without label or name He had not heard that the police had had great difficulty in tracing it in poison cases In answer to a question by the President he admitted having heard of the regulations since this complaint had been brought against him. Although this *particular Jeyes' fluid* had been there for his own use, he had some for sale as well.

Mr. T Armstrong, M.P S, Dr Crombie's dispenser, stated that the assistant knew what she could sell and what she could not He had removed all dangerous poisons from her care as soon as he had taken over the dispensary Cross-examined, he stated that he did not understand that Jeyes' fluid was a dangerous poison. He had given the assistant no special directions about Jeyes' fluid or lysol The inspector had asked for lysol, and the assistant, not having any, had recommended Jeyes' fluid, which she had sold in an unlabelled bottle It was left to her to do the labelling

In reply to a question by the President witness stated that he was responsible for the conduct of the *dispensary*; he went there several times a week, but it was kept open without him The assistant who was employed by the respondent was in charge when neither of them were there

Dr Hamilton stated in his defence that his assistant's only duties were to open and close the surgery, and to sell a few tooth-brushes and tubes of paste The whole stock was only worth 2½ guineas She had a list of things she was allowed to sell and had been warned not to touch poisons of any sort. What lysol he had was for his own use, and not for sale and was therefore unlabelled. He did his own dispensing The assistant would get half the profits from her sales

Mr. Hempson pointed out, for the defence, that although ignorance of the law was no excuse, there was a ready sale of Jeyes' fluid and lysol, *which many* people did not know were scheduled poisons He produced a bottle of Jeyes fluid which he had bought *that day* On the President pointing out that there were two grades of this fluid, he could not answer for which his specimen might be

The Council found the facts alleged against the respondents proved to their satisfaction The practice of allowing unqualified assistants to sell these disinfectants, said the President, was fraught with danger to the public and not creditable to the medical profession He quoted from the Council's Warning Notice Having regard, however, to the regrets expressed by the respondents and their pledges to amend their precautions against this abuse, the Council would postpone judgment for six months, subject to the usual provisos

The Case of Duncan Miller, registered as of Glebe House, Washington, Co Durham M B, Ch B, 1911, Aberd The charge was that of having been convicted of being drunk whilst in charge of a motor-car, and on another occasion of having been found drunk on the highway Respondent stated that since he had had malaria he had been very susceptible to alcohol Since the last conviction, in December, 1926, he had been a complete abstainer The Council decided to suspend judgment until May, 1928, but warned him that any conviction in the interval might cause his name to be erased at once

Public Health Services.

DIAGNOSIS OF SMALL-POX IN LONDON
“MISSED” CASES

THE London County Council has issued a reminder to all practitioners within its area that in recent years outbreaks of small-pox have occurred through the agency of “missed” cases In view of the importance, therefore, of securing the early recognition and diagnosis of small-pox, the Council draws attention to the desirability of conferring at once with the medical officer of health *of the borough concerned* in all doubtful cases and also of ensuring that no case is removed to hospital without first consulting the medical officer If difficulty should arise in securing immediate touch with the M O H the services of Dr W McConnel Wanklyn will be available at any time of the day or night and during week-ends, on application to the Public Health Department, County Hall, Westminster Bridge, S E 1 (Telephone Hop 5000)

SPECIAL SCHOOLS

THE Board of Education's list[1] of special schools and institutions for defective children is interesting as showing what progress has been made The amount of this progress varies greatly in different parts of the country In some areas the authorities have no establishments of their own and make use to some extent of those belonging to their neighbours—an arrangement that has many disadvantages The grouping under counties, moreover, does not give an accurate picture of the true state of affairs, for example, some of the special schools in Kent belong to outside authorities such as the London County Council, whilst others are maintained by borough and urban district councils and not by the county authority Similarly, the Soss Moss School for Epileptics is given under Cheshire, though a footnote explains that it is maintained by the Manchester Education Authority

Speaking generally there is nearly enough accommodation for the totally blind and deaf, but great benefit would result from earlier admission, for all experts agree that deaf children ought to begin their training much earlier if they are to acquire good speech There is a great lack of accommodation for the mentally defective children, less than a half of them are dealt with, and a large proportion of the places provided for them are concentrated in a few places like London, Manchester, Liverpool and Birmingham, whilst whole counties like Cumberland and Cornwall have no special schools for these children within their borders Even where there are some day special schools the problem cannot be considered as completely solved The most troublesome feature of many of these children is instability, and where this character is strongly marked residential school-care is necessary Apart from residential schools, those offering the best promise for the future are the ones which give manual work and elementary industrial training to the elder mentally defective pupils It is sometimes suggested that it is an economic advantage to let these children go into industry at the age of 14 because employers will then be more ready to accept them But the very reason which makes employers accept children at this age causes them to get rid of the same children when they are 16, and they are then thrown upon the world unemployed and untrained The additional two years of manual and moral training makes a difference to their future both as regards the capacity for permanent employment and the control of antisocial tendencies

Much more provision, too, is needed for the physically defective, and in these cases it is more obvious though probably no more true, that expenditure on salvage is the best economy Orthopædic schools and residential open-air schools in particular repay their cost, often changing a weakly child from a burden to the community into a valuable worker and citizen Accommodation is most of all seen to be lacking for epileptics Assuming that 0 6 per 1000 of the child population are affected, the number to be dealt with would be about 3000 but the figures given in the list (p 31) shows that the total provision is for 525 cases only Lastly, there is scarcely any mention of provision for those difficult cases of double defect Apparently the only establishments dealing with this problem are the school at Penn (Buckinghamshire), maintained by the L C C for the mentally defective and deaf, and the little Ellen Terry Home at Reigate for the blind and mentally defective, at which there are at present only five pupils

INSTITUTE OF HOSPITAL ALMONERS

A MEETING was held in support of this Institute on May 26th at the Grotrian Hall, Wigmore-street, Lady (ROSE) BRADFORD, the President of the Institute, being in the chair

Dr CHARLES GRAY, chairman of the Council, briefly surveyed the history of the movement, which was largely due to the inspired enthusiasm of the late Sir Charles Loch The first almoner was appointed at the Royal Free Hospital in 1895, and the Hospital Almoners Council was formed ten years later Originally it had been supposed that any woman with sympathy and brains could do the work, but it soon became obvious that special training in the science of charitable assistance must be undertaken if the community on the one hand, and the patients on the other, were to get the utmost advantage from the efforts of the almoner The course of study organised by the Institute was originally of three months' duration but had been extended from time to time, and now it covered 2 to 3 years Theoretical instruction at a school of economics combined with visits to charity organisation associations was followed by a term of practical work under the supervision of a trained almoner in a hospital The scope of the work done by the almoners had extended in recent years from out- to in-patients, and thence to the special departments and the maternity districts and a further enlargement of the sphere of their activities to include Poor-law infirmaries mental hospitals, tuberculosis dispensaries, and institutions for the feeble-minded was to be anticipated

---

[1] Certified Special Schools Recognised Institutions for the Training of the Blind and other Defective Children and Nursery Schools in England and Wales List 42 1927 H M Stationery Office 1s

SIR **JOHN ROSE BRADFORD** spoke on the relation of almoners' work to medicine The advance of medicine in recent years was due not only to improved methods of technique and nursing, but also to the development of a system of after-care It was in this direction that almoners did so much useful ancillary work Treatment used to be confined to periods of illness, if not even actually to the acute stage of illness, but it was now recognised that many diseases were less formidable in the acute stage than they were later on, and intelligent observation was needed long after the hospital stage if the utmost benefit from treatment was to be secured The need for after-care had long been recognised for discharged mental cases and was now considered essential for many diseases affecting the body, such as acute rheumatism Sufferers from chronic diseases could often be maintained in fair health if supervised A trained almoner could afford great help in the investigation of disease, whereas an untrained one could not effectively cooperate in medical research

SIR **BERKELEY MOYNIHAN**, in corroborating Sir John Rose Bradford, said that he was glad to fulfil this function of a surgeon, who was often called in to demonstrate the accuracy of teaching and prediction made by a physician He added that something more than medical and surgical efforts were needed in hospital work, which was concerned not only with momentary restoration of health to individuals, but with the retention of efficiency in a unit of the industrial army In surgery the ultimate outcome was more important than the immediate result, and after-care was urgently needed The doctor might order rest, change, or apparatus which the patient could not possibly secure unaided, his instructions often seemed unintelligible and his suggestions impracticable until they had been interpreted by the almoner As to preventive work, patients sometimes presented themselves at hospital in such a debilitated condition that the almoner had to devise means to restore their vitality before treatment could be given The public ignorance of fundamental facts was still so great that it was hardly an exaggeration to say that a multitude of people either committed suicide or were murdered In order to fulfil her function as an ambassador of medicine on the domestic hearth an almoner must be a specially trained gentlewoman moved not by sterile pity but by active compassion She had to be the ambassador not only of the doctor, but of the community It was her business to be cognisant of all the agencies which might play a part in promoting the welfare of a patient and to see that he was in a position to take advantage of them There was at present much talk of the possible future administration of Poor-law hospitals by city councils The Government might with advantage give a lead in insisting on the appointment of almoners to such institutions and induce the public and the governing bodies of hospitals to realise that without trained almoners on the staff their work was not fully effective

SIR **ARTHUR STANLEY** spoke from the standpoint of a hospital treasurer It used to be thought that the chief value of an almoner was to prevent abuse of the hospital This was certainly one of her functions but gross attempts by the well-to-do to get hospital attention were nowadays rare After the war the financial condition of St Thomas's Hospital was at a low ebb The almoners explained the situation to the patients, with the result that the income derived from their contributions rose from £1400 to £14,000 Sir Arthur Stanley quoted a letter from Dr John Fairbairn referring to the value to medical students of the collaboration of the almoner

SIR **STCLAIR THOMSON** proposed a vote of thanks to the speakers and the President, and Lady Bradford replied

"Audi alteram partem"

THE PURITY OF ANÆSTHETIC ETHER

To the Editor of THE LANCET

SIR,—Dr. S R Wilson's paper on "ether" convulsions in last week's issue is of importance not only because it demonstrates convincingly the cause of these convulsions, but because it draws attention to a much-neglected subject—namely, the purity of ether Probably the reason of this neglect is in the first place the lack of tuition in the clinical period, and in the second place an optimistic reliance by anæsthetists and hospital pharmacists on the distinctly florid descriptions attached by some manufacturers to their products Even Dr Wilson seems to have been hypnotised There is the less reason for this attitude, for Mr H Finnemore in 1914, at that time senior pharmacist to Guy's Hospital, read a paper on Anæsthetic Ether of Commerce before the British Pharmaceutical Conference,[1] and another on the same subject before the Section of Anæsthetics of the Royal Society of Medicine in 1915,[2] whilst Mr G. Middleton also discussed the subject fully in 1924 at the British Pharmaceutical Conference [3]

The method recommended by Finnemore for selecting a methylated ether has given complete satisfaction at Guy's The ether is chosen after a series of tests from samples supplied by the leading manufacturers, a contract is then placed for the year and the ether is delivered monthly and tested on delivery The tests used for peroxides are the alkaline potassium permanganate solution (suggested by Finnemore), the vanadic acid, and the cadmium potassium iodide tests, and for aldehydes the reaction with solid potassium hydroxide, which is allowed to remain in contact with the ether for at least six hours, although the B P only requires a time-limit of one hour The result of this constant care is that the manufacturers are kept up to the mark, and on only two, or at the outside three occasions, has the ether been returned for further purification But it is not intended to remain content, methylated ether can be made to reach a higher standard It is a question of the selection of the most stringent tests for peroxides which are also of easy application But here one must be careful, for as ether is an unstable body and has to be sent on long voyages, too high a standard must not be demanded of the B P

As regards decomposition of ether in my apparatus may I refer Dr Wilson to an article in your columns [4] describing this apparatus, in which I drew attention to the importance of testing the ether, before and after use, for peroxides and aldehydes, and stating that my practice was to use the ether twice, as the result of many tests had shown that a pure ether did not develop aldehydes and only occasionally peroxides after the first case But this article did not contemplate the recent modification which substitutes for the hand-bellows—an instrument which demands a small output of energy—the easy, effortless, continuous stream of oxygen I believe this method to have inherent dangers for, owing to hyperoxygenation, the signs of an overdose are easily masked Further, the tendency to decomposition is increased although, of course, no decomposition of a pure ether takes place in a reasonable time For example, I have on a recent afternoon used the same ether, vaporised by oxygen and exposed to a strong light for three consecutive major operations, a few ounces of fresh ether were added to the bottle before the last case, an amputation of the breast The ether was then tested and found to be free from peroxides and aldehydes Dr Wilson bubbled oxygen through ether for two hours in an artificial light and found that decomposition had been rapid and great, this ether, however, was impure to start with, and it is known that decomposition once started goes on rapidly under favourable conditions Of these conditions the most important is the presence of light, and I think Dr Wilson's suggestion of amber-tinted bottles for my apparatus is good, especially for hospitals The British Drug Houses, Ltd, kindly conducted for me in 1921 the experiment of bubbling oxygen through their highly purified ether for a considerable time—viz, four hours—but the apparatus was protected from light The vapour was condensed and collected in two fractions. Each of the fractions and the residue were found to be free from peroxides and aldehydes

[3] Pharm Jour, July 26th, 1924

[4] THE LANCET, 1916, i, 70

Dr Wilson's precautionary measures include the discarding of "stale" ether, but he does not define "stale" I should like to suggest that the odour is a useful guide An ether, a few c cm of which when allowed to evaporate from the hand give a disagreeable or pungent odour, should be discarded Some ethers are not free from this odour on delivery, they should be rejected Four specimens of used ether, three of which had been allowed to stand in my apparatus for 24 hours, were tested recently for impurities, two, which gave on evaporation this characteristic odour, also gave positive reactions for aldehydes and peroxides, two, which were free from odour, were also free from impurities

I am, Sir, yours faithfully,
May 28th, 1927 FRANCIS E SHIPWAY

THE EMPLOYMENT OF MARRIED WOMEN

The Editor of THE LANCET

SIR,—In your leading article of May 14th you refer to the action of the Durham County Council in dismissing the married women officers on its medical staff The following is a copy of the resolution passed by the Council to which your article refers —

> "That the County Council give three months' notice terminating the appointment of all married women officers on its medical staff whose husbands are in receipt of an adequate income, and that in future no married women be given appointments on the medical staff of the department whose husbands are in receipt of an adequate income"

As a result of the passing of this resolution I have been dismissed from my appointment as assistant maternity and child welfare officer to the Durham County Council I have since applied for a similar post under the Finsbury Borough Council and my application was returned immediately as "ineligible" I know there are several other boroughs which object to married medical women on their staff, and the Ministry of Health itself leads the way in refusing to employ married women I feel it will be difficult, if not impossible, to obtain other employment in the Public Health Service Apparently this service is not open as a career for medical women unless they are prepared to remain unmarried

The whole question of the employment of married women bristles with difficulties, mostly imaginary The objection of the Durham County Council to the husband being in possession of an adequate income seems a typical example of such a "difficulty" There seems to be a strong public opinion amongst the laity against the employment of married women The point of view of the medical profession is, of course, different It is obviously against the honour and interest of that profession that it should be entered by a number of women who intend to give up their work on marriage and merely regard medicine as an interlude until such an event occurs

This is a matter to be taken up primarily by medical women themselves It is clearly unjust that they should be allowed to take medical degrees and the D P H and later be shut out from a large sphere of practice such as the Public Health Service

I am, Sir, yours faithfully,
ELEANOR C E MCINTOSH, M B, B S., D P H
Bishop Auckland, May 29th, 1927

THE REGISTERED NURSES' BUREAU

To the Editor of THE LANCET

SIR,—As chairman of the honorary advisory committee of the Registered Nurses' Bureau, I have to-day received a letter from Messrs A Wander, Ltd, in which they state that they are making a contribution of £1000 towards its expenses "We are prepared," they say, "to guarantee the Bureau financially over a period of two years, by which time we are confident that the recognition, approval, and support of your own profession will have placed its help beyond question"

In connexion with this handsome donation, which will, I am sure, be deeply appreciated by the medical and nursing professions, may I make two observations? (1) Too few of my colleagues realise that the majority of the devoted women who nurse their patients are paying heavy weekly commissions on their all too meagre remuneration, and that, to private concerns which thus exploit them The Bureau eliminates that I cannot too strongly urge all my professional confreres to acquaint themselves with the work of the R N B and to cooperate in this endeavour to help in a real and practical way the nurses on whom they depend so much (2) The R N B. is occupied only with the work of the private State-registered nurse—and in London only for the moment It steers clear of, and touches upon no controversial subject, and has no political or factional bias or affiliation The recognition, approval, and support of the medical profession will ensure the success of its work, and I appeal, therefore, to all medical men to accord that support wholeheartedly

The registrar will gladly send full information to any medical man or to any member of the public. The address of the Bureau is 55, Chancery-lane, W C 2 Telephone. Holborn 6846

I am, Sir, yours faithfully,
W ARBUTHNOT LANE

IODINE

To the Editor of THE LANCET

SIR,—My attention has been drawn to the review in your issue of May 21st (p 1114) of my paper on the Use of Iodine in Various Deficiency Diseases. The publication has been widely quoted in the lay press from Australia to the United States, and has brought me many hundreds of letters from medical men and women and others The only instances of damning with faint praise have been your review and that in one other medical paper Perhaps it is natural that this should be so, and I only write because I do not accept two phrases in your criticism as fair comment

The first is "research workers may look somewhat askance at his 'some hundreds of cases' *without recorded controls*" (the italics are mine) My report deals mainly with common ailments of childhood—debility, backwardness, chronic bronchitis, nocturnal incontinence, worms, boils, and the like—and not with fancy diseases Such conditions are prevalent everywhere, and are certainly common in Cumberland For years before the use of iodine was started all recognised forms of treatment were employed in our school clinics for these conditions Since we began to use iodine so many of each class have been treated on the old lines, so many on iodine in one form or other The results have been compared; the record cards of both groups are available for reference at any time If this procedure does not provide "recorded controls" then I do not understand the meaning of "control" If, further, as is the case, my colleagues here—men of up to 12 years' experience of school medical work—have, as a result of their comparisons of the results of the two lines of treatment, unanimously discarded the old method in favour of iodine treatment in many conditions—e g, worms, incontinence, backwardness, chronic bronchitis, &c, that, I think, is good evidence

The second phrase I query is "his rather undiscriminating choice of references to the value of iodine in disorder of all kinds" Strongly believing, as I do, in the value of iodine therapy I endeavoured in this report, to collect so far as I could all possible references to the use of iodine for all sorts of conditions and to give the fullest information as to lines of treatment, and as to *alleged* beneficial results, not that I believe them all, but to lay a foundation on which others desiring to further investigate the matter might build, and nothing more.

The report is a reprint, and was written in the first place for a lay committee and the criticism of the first report by medical men which reached me was that I did not sufficiently outline the 'how, the why, and the wherefore" of the matter. In other words, I was asked to set out clearly the *possible* indications for the use of iodine and the exact methods Hence the matter contained in the reprint. Being anxious to avoid the risk of the somewhat obvious and superficial jibe that one was propounding a 'cure-all remedy, I was particularly careful in the wording of the report That this was recognised in some quarters may be demonstrated by a quotation from the editorial comment in the *Municipal Journal*:

Dr. Fraser is expert in the moderate statement of his case You apparently do not share this view

The value of the claims is open to test. I say quite definitely, for example that boils will readily yield to collosal iodine in appropriate doses that threadworms are quickly cured by iodised butterscotch, that the nocturnal incontinence of children will in all cases be much reduced and in nearly all cases cured by either of the above. These claims are straightforward and easily tested If they prove reliable many of the other claims are no more difficult of trial and I have no remotest doubt that a fair test will lead to a revision of the verdict "Not proven which no doubt arises not from any weakness in the case for iodine, but from my imperfect statement of it I am, Sir, yours faithfully

Carlisle May 24th 1927 KENNETH FRASER

MEDICAL LITERATURE FOR KENYA COLONY

To the Editor of THE LANCET

SIR,—May I ask your help in making known a need of one of our latest outposts of Empire?

The Hon Lady Grigg, wife of the Governor of Kenya, finding a serious deficiency of nursing aid for both white settlers and natives in the colony, has established a nursing institute which is already doing excellent work but requires further support Among other appliances for which there is pressing need are medical books and a supply of these would be gratefully welcomed not only by the nurses but by the doctors working amongst this rapidly growing population Lady Grigg has asked the Victoria League which has already sent out works of general literature, whether it could supplement these by a gift of books dealing with nursing medicine, and surgery If any of your readers should have works on these subjects which they no longer require and which are in good condition and fairly up to date, they would be rendering valuable help if they would send them addressed to me, Dowager Countess of Jersey, President Victoria League 81, Cromwell-road S W 7 I would thankfully acknowledge any such gifts I am, Sir, yours faithfully,

M E JERSEY

Victoria League House 81 Cromwell road, S W 7

CHILL DURING ULTRA-VIOLET TREATMENT

To the Editor of THE LANCET.

SIR,—I should like to draw the attention of ultra-violet radiologists to a manner in which I think their ministrations to sufferers from neuritis and kindred ailments are handicapped. With considerable experience of the treatment as administered in London, the provinces, and on the continent, I have learnt that insufficient attention is paid to the temperature of the room in which the treatment is given In order to get the best results and to avoid aggravating the symptoms, or even adding other ailments to that from which the patient is suffering it is essential that the temperature of the room should be maintained at such a level as will enable the patient to lie, in absolute comfort in a state of nudity, without any feeling of chilliness, and that all possible sources of draught should be excluded This is also true even when only a portion of the body is exposed

I have several cases in my mind where I am persuaded pain has been increased not alleviated, by the treatment simply and solely because during its exhibition they were positively shivering with cold And in two cases attacks of bronchitis intervened in elderly patients after seances from the same cause I am confident that ultra-violet treatment should always be administered in well-ventilated rooms provided with means for keeping them at a regular and decidedly warm temperature, and be free from all sources of draught Inattention to these details seems to be prevalent

I am, Sir, yours faithfully,

LEONARD MOLLOY

Harley street, W May 24th, 1927

THE *BACTERIUM PNEUMOSINTES*

To the Editor of THE LANCET.

SIR—We have read with great interest the account of the recent work of Dr G S Wilson in attempting to isolate *B pneumosintes* from cases of influenza during the recent epidemic (THE LANCET, May 28th p 1123).

We have ourselves been carrying out a similar investigation for the Medical Research Council, the results of which it is hoped to publish shortly. In the meantime we wish to record the fact that we also have been unable to isolate *B pneumosintes* in any of the 12 cases we have investigated.

We are Sir yours faithfully,

RONALD G CANTI,
LAWRENCE P. GARROD,
T MEYRICK THOMAS

London, E C, May 30th, 1927

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 21ST, 1927.

Notifications—The following cases of infectious disease were notified during the week:—Small-pox, 313 (last week 271), scarlet fever, 1513, diphtheria, 839 enteric fever, 57, pneumonia, 939; puerperal fever, 41, puerperal pyrexia 94; cerebro-spinal fever, 11 acute poliomyelitis 6; acute polio-encephalitis 1, encephalitis lethargica, 38, dysentery, 5, ophthalmia neonatorum, 120

Cases of small-pox were notified from the Counties of London 1 (Hackney) Derby 5 Durham 152 Lancaster 7, Middlesex 1 (Southall Norwood), Northumberland 29, Nottingham 5, Yorks, West Riding 59, Monmouth 54

Deaths—In the aggregate of great towns including London there were no deaths from small-pox, 1 (1) from enteric fever 57 (2) from measles 12 (0) from scarlet fever, 31 (13) from whooping-cough, 18 (6) from diphtheria, 43 (3) from diarrhœa and enteritis under two years and 46 (7) from influenza. The figures in parentheses are those for London itself

PRESENTATION TO A MEDICAL MAN—The Board of the Manchester Victoria Jewish Hospital on May 29th gave a lunch and made a presentation to Dr Nathan Charles Haring who has been honorary physician to the hospital since its opening in 1904, and the chairman of its medical board A further memorial to Dr Haring's work is the foundation of a bed in the hospital to be named after him.

artificial light and found that decomposition had been rapid and great; this ether, however, was impure to start with, and it is known that decomposition once started goes on rapidly under favourable conditions. Of these conditions the most important is the presence of light, and I think Dr. Wilson's suggestion of amber-tinted bottles for my apparatus is good, especially for hospitals. The British Drug Houses, Ltd., kindly conducted for me in 1924 the experiment of bubbling oxygen through their highly purified ether for a considerable time—viz., four hours—but the apparatus was protected from light. The vapour was condensed and collected in two fractions. Each of the fractions and the residue were found to be free from peroxides and aldehydes.

Dr. Wilson's precautionary measures include the discarding of "stale" ether, but he does not define "stale." I should like to suggest that the odour is a useful guide. An ether, a few c.cm. of which when allowed to evaporate from the hand give a disagreeable or pungent odour, should be discarded. Some ethers are not free from this odour on delivery; they should be rejected. Four specimens of used ether, three of which had been allowed to stand in my apparatus for 24 hours, were tested recently for impurities; two, which gave on evaporation this characteristic odour, also gave positive reactions for aldehydes and peroxides; two, which were free from odour, were also free from impurities.

I am, Sir, yours faithfully,

May 28th, 1927. FRANCIS E. SHIPWAY.

THE EMPLOYMENT OF MARRIED WOMEN

The Editor of THE LANCET

SIR,—In your leading article of May 14th you refer to the action of the Durham County Council in dismissing the married women officers on its medical staff. The following is a copy of the resolution passed by the Council to which your article refers:—

> "That the County Council give three months' notice terminating the appointment of all married women officers on its medical staff whose husbands are in receipt of an adequate income, and that in future no married women be given appointments on the medical staff of the department whose husbands are in receipt of an adequate income."

As a result of the passing of this resolution I have been dismissed from my appointment as assistant maternity and child welfare officer to the Durham County Council. I have since applied for a similar post under the Finsbury Borough Council and my application was returned immediately as "ineligible." I know there are several other boroughs which object to married medical women on their staff, and the Ministry of Health itself leads the way in refusing to employ married women. I feel it will be difficult, if not impossible, to obtain other employment in the Public Health Service. Apparently this service is not open as a career for medical women unless they are prepared to remain unmarried.

The whole question of the employment of married women bristles with difficulties, mostly imaginary. The objection of the Durham County Council to the husband being in possession of an adequate income seems a typical example of such a "difficulty." There seems to be a strong public opinion amongst the laity against the employment of married women. The point of view of the medical profession is, of course, different. It is obviously against the honour and interest of that profession that it should be entered by a number of women who intend to give up their work on marriage and merely regard medicine as an interlude until such an event occurs.

This is a matter to be taken up primarily by medical women themselves. It is clearly unjust that they should be allowed to take medical degrees and the D.P.H. and later be shut out from a large sphere of practice such as the Public Health Service.

I am, Sir, yours faithfully,

ELEANOR C. E. MCINTOSH, M.B., B.S., D.P.H.

Bishop Auckland, May 29th, 1927.

THE REGISTERED NURSES' BUREAU

To the Editor of THE LANCET

SIR,—As chairman of the honorary advisory committee of the Registered Nurses' Bureau, I have to-day received a letter from Messrs. A. Wander, Ltd., in which they state that they are making a contribution of £4000 towards its expenses. "We are prepared," they say, "to guarantee the Bureau financially over a period of two years, by which time we are confident that the recognition, approval, and support of your own profession will have placed its help beyond question."

In connexion with this handsome donation, which will, I am sure, be deeply appreciated by the medical and nursing professions, may I make two observations? (1) Too few of my colleagues realise that the majority of the devoted women who nurse their patients are paying heavy weekly commissions on their all too meagre remuneration, and that, to private concerns which thus exploit them. The Bureau eliminates that. I cannot too strongly urge all my professional confrères to acquaint themselves with the work of the R.N.B. and to cooperate in this endeavour to help in a real and practical way the nurses on whom they depend so much. (2) The R.N.B. is occupied only with the work of the private State-registered nurse—and in London only for the moment. It steers clear of, and touches upon no controversial subject, and has no political or factional bias or affiliation. The recognition, approval, and support of the medical profession will ensure the success of its work, and I appeal, therefore, to all medical men to accord that support wholeheartedly.

The registrar will gladly send full information to any medical man or to any member of the public. The address of the Bureau is 55, Chancery-lane, W.C. 2. Telephone: Holborn 6846.

I am, Sir, yours faithfully,

W. ARBUTHNOT LANE.

Cavendish-square, W., May 30th, 1927.

IODINE

To the Editor of THE LANCET

SIR,—My attention has been drawn to the review in your issue of May 21st (p. 1114) of my paper on the Use of Iodine in Various Deficiency Diseases. The publication has been widely quoted in the lay press from Australia to the United States, and has brought me many hundreds of letters from medical men and women and others. The only instances of damning with faint praise have been your review and that in one other medical paper. Perhaps it is natural that this should be so, and I only write because I do not accept two phrases in your criticism as fair comment.

The first is "research workers may look somewhat askance at his 'some hundreds of cases' *without recorded controls*" (the italics are mine). My report deals mainly with common ailments of childhood—debility, backwardness, chronic bronchitis, nocturnal incontinence, worms, boils, and the like—and not with fancy diseases. Such conditions are prevalent everywhere, and are certainly common in Cumberland. For years before the use of iodine was started all recognised forms of treatment were employed in our school clinics for these conditions. Since we began to use iodine so many of each class have been treated on the old lines, so many on iodine in one form or other. The results have been compared; the record cards of both groups are available for reference at any time. If this procedure does not provide "recorded controls" then I do not understand the meaning of "control." If, further, as is the case, my colleagues here—men of up to 12 years' experience of school medical work—have, as a result of their comparisons of the results of the two lines of treatment, unanimously discarded the old method in favour of iodine treatment in many conditions—e.g., worms, incontinence, backwardness, chronic bronchitis, &c., that, I think, is good evidence

Rejection of the Bill Moved

Lord BANBURY, in moving the rejection of the Bill, said that one of its main features was a proposal to impose a charge or tax on certain members of the community He did not believe that their lordships had any power to impose a tax on any section of His Majesty's subjects He had always understood that the only body that could do that was the House of Commons and even in the House of Commons a tax could not be imposed unless it was proposed by the Government. If the Bill reached the House of Commons unless it was taken up by the Government he did not believe that it would pass. There was an absolutely identical Bill in the House of Commons introduced by a Socialist Member The names on the back of the Bill were one Socialist, one Liberal and Viscountess Astor. He (Lord Banbury) thought there could be no doubt that this was the Bill of Viscount Astor. and he would ask him why he did not bring it in himself Why did he hide behind a bishop? He did not call the provisions of this Bill popular control. He would like to use rather strong language about it if it had not been introduced by the right reverend prelate. If it had been introduced by Lord Astor he would say that it was a gerrymandering Bill It was a bad Bill, and it was very doubtful whether it would stop drinking If it did so the Board would be bankrupt, and he thought, therefore, that they had far better leave people to drink as much or as little as they liked. He had with him the statistics for 1925 of drunkenness in America which was a prohibition country, and these showed that the drunkenness in America was far greater than in England He thought that practically every country which had been foolish enough to enact a law of this kind had either reversed it or was going to reverse it

Two Aspects of the Drink Question.

Viscount ASTOR said that if he were the real father and author of the Bill he would not be attempting to hide behind anybody else. He would support almost any measure for progress, or almost any temperance proposal except a Bill to impose prohibition on the nation He wanted to make that quite clear He supported the Bill before the House because he thought it provided a constructive proposal for dealing with two aspects of the drink question There was what he called the alcohol question—that was to say the social evils which came from the unwise consumption of alcohol· and there was the question of the influence on the national life exercised by the drink trade. These were entirely different questions and the Bill made a real constructive proposal for dealing with both The commercial interest of the trade, organised as now on a competitive basis, was to stimulate the very maximum of consumption of intoxicants Those who were interested in the temperance question welcomed the fact that the nation was much more sober than before the war The Southborough Committee indicated the other day that we were more sober now because Parliament had reduced the number of hours during which drink might be sold, and had increased the price which the public had to pay That was to say that various Acts of Parliament which had been passed had increased the sobriety of the nation but they had all been opposed by the whole strength of the drink trade At the present moment the trade was doing all it could to abolish some of the Acts which had made the country more sober If they did so they would diminish the national sobriety Although the alcohol question was much better than it was it was still a problem, and drink was still a factor in the causation of our social ills. The trade had been kind enough to say that he ought to be kicked out of the Conservative party because he supported the heads of the churches on temperance reform. He hoped they would change their attitude, because with the new electorate the Conservative Party would find that they were standing on a shakier platform than in the past if they relied wholeheartedly on the support, coöperation, and direction of the licensed trade, since the people were realising that it was impossible to reconcile national interests with those of the licensed trade. The influence of the drink trade in public life had been condemned not only by Lord Rosebery but by other prime ministers He asked their lordships on which side they were going to be on the side of the trade or on the side of the State? He would not discuss the merits or demerits of alcohol. A committee of experts under the Privy Council had done this very fully, and he thought he could summarise what those experts said by indicating that in their opinion alcohol, broadly speaking was the alternative to effective performance Lord Dawson of Penn had indicated some of the value of alcohol as he saw it. As he (Lord Astor) remembered, Lord Dawson said that where one had dull speakers at a public banquet and one wanted to keep people amused and interested alcohol made them think that they were witty although they naturally did not possess wit· that where there were people who were not drinking alcohol they were dull whereas at an adjoining table where people were drinking alcohol they found wit and sparkle He thought that Lord Dawson also indicated that in the stress of modern life with all its rush and bustle if people insisted on what was called burning the candle at both ends alcohol might be a help How desirable it might be for people to go on burning the candle at both ends he (Lord Astor) did not know The more he studied the drink question he said frankly the less he was ready to be dogmatised in what was the right solution for any locality If the policy of "no licence" was wrong it could not win but if it was right they could not stop it. In his public life he had two great principles which had helped him through One was an abiding faith in the commonsense and patriotism of the British public and the other was an increasing realisation that right must always overcome wrong If their lordships had the same feeling they could support this Bill with confidence and without fear

Drunkenness Out of Fashion

Lord DESBOROUGH speaking on behalf of the Government said that he believed in elevating the whole tone of the people, and that had been done in a remarkable way for many years Drunkenness in this country had gone out of fashion among all classes and if they put down the great improvement in that respect merely to certain Acts of Parliament or to certain systems of licence which had been introduced since the war he thought that they were overlooking the great and gratifying fact that it was really the feelings of the people which had introduced this very great improvement in the habits of the people. He believed it was a wrong system to try to make people good by the votes of those with whom they did not agree Such a system had always failed The right way was by reason and argument to educate public opinion The Southborough Committee said in their report —

> We are of opinion therefore that while the schemes of State management at Carlisle Gretna and Cromarty Firth have already produced results which are of value much still remains to be done for the purpose of ascertaining what system or type of public house provides for the legitimate needs of the people without encouraging or fostering excessive drinking We are not satisfied that the case has been established for the extension of the schemes to any other particular area or place

As far as he could see those remarks would equally apply to a system of public management The Southborough Committee also added in reference to these schemes and he thought this was of importance —

> We are of opinion that they should be continued, and that the work on which they are engaged should proceed until such time as it is possible to make a more final estimate of the results which have been achieved "

That rather summed up the attitude of His Majesty's Government on this portion of the Bill—namely a provision for a vote on public or State management The Government could not at the present time without a great deal of further inquiry support any scheme of absolutely stopping licences with a time limit as suggested in this Bill The Government were and had been considering this very important and difficult question but they were not at present in a position, and would not be until much further investigation was made to draw up a Bill dealing with the matter though they hoped to review the whole subject at the earliest possible moment

The Removal of Temptation

The Duke of MONTROSE said he was just as fond of a glass of wine as any noble lord who hoped to kill this Bill, but he did recognise that there was in this country an evil of intemperance, and that there was an agitation to do something to remove that evil It was wise practical, and possible to favour a measure such as the one under discussion which while it preserved freedom of opinion for the community allowed them to do away with the undesirable temptation to push the sale of liquor for unlimited and unrestricted gain

Viscount SUMNER said that he gave every credit to the assumption that with trial and error it might be possible to run the system of public management with a moderate amount of public satisfaction But before that could be such a success as to be any substitute for the present system many years must elapse and he thought that those who were quite as earnest in the cause of temperance as the societies and speakers of whom they heard a great deal, would agree with him in saying that the wisest course they could pursue was to attack this evil indirectly It was to the spread of education, to the rise in wages to the training which was to be got in the judicious use of leisure that they must look for an extensive improvement in temperance

The Bishop of BRADFORD said it was a remarkable fact that every single denomination who belonged to the Temperance Council of the Christian Churches of England and Wales had given its approval to this particular Bill after careful consideration

On the motion of the Earl of PLYMOUTH the debate was adjourned until Tuesday, June 21st

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

VACCINATION BILL

THE text of the Bill introduced in the House of Commons by Mr GROVES to amend the law relating to compulsory vaccination has now been issued It provides that no person shall be subjected to any penalty or loss or disability of any kind for refusing to be vaccinated, or for refusing to cause any child or young person to be vaccinated No payment in respect of vaccination is to be made out of moneys voted by Parliament, or out of any local or general rate Sections 29 and 31 of the Vaccination Act, 1867, and Section 1 (3) of the Vaccination Act, 1898, are repealed by the Bill The Act is intended to come into operation on January 1st, 1928

HOUSE OF LORDS.

TUESDAY, MAY 24TH

LIQUOR (POPULAR CONTROL) BILL

The BISHOP OF LIVERPOOL, in moving the second reading of the Liquor (Popular Control) Bill, said the measure was first introduced three years ago by the late Bishop of Oxford, Dr Burge During the debate in 1924 the view was expressed that the Bill could best be improved not in Committee but by making a fresh draft and presenting it again That had been done, but the main principles remained as before The first was that there was a need and an opportunity for further legislation in this matter There was in this country a vast amount of drinking, doing a vast amount of harm, but not amounting to what the police called drunkenness and not ending in the police courts The progress that had been made during the last 20 years in this matter he willingly and thankfully acknowledged There was a decrease in drunkenness which could be proved, he thought, by figures, there was also something which could not be proved by figures, but must be a matter of opinion His impression was that there was an increase in sobriety, which was a very different thing The people of the country were realising two things The first was that an increase in sobriety—he did not mean decrease in actual drunkenness—meant an increase in efficiency, in national wealth and in public welfare, and the second was that there were powerful and quite artificial obstacles in the way of this progress People were asking why these obstacles could not be removed and why they could not be made free to drink as much or as little as they liked There were two ways of meeting that appeal In the first place they might impose upon the whole country a single solution to be applicable equally in every part That meant waiting until temperance reformers and other people were agreed as to what the solution should be and that was not a very near prospect The second method of meeting it was by conferring upon the inhabitants of local areas the right and responsibility of deciding how and to what extent liquor should be manufactured and distributed in their area That was the method of the Bill, which made possible a series of experiments from the experience of which the country might ultimately be able to proceed to a single uniform solution for all areas The areas were at present the City of London and the electoral divisions or in the provinces the county boroughs, municipal boroughs with a population of 50,000 and more, the existing licensing districts, and new housing districts which contained more than 1500 houses The franchise was the Parliamentary franchise, and the arrangement was that there should be a first preference and an alternative vote if the first preference was not carried That was to prevent the decision being made by a real minority of the voters

A "Local Option" Bill

The Bill was a true Local Option Bill Three choices were given The first was "no change," and a bare majority would preserve the status quo The next choice was what was called "reorganisation" There might be a certain number of areas in which people would say something like this "We want reasonable opportunities for drinking but we do not want to minister to the private interest of any individual or any company by having the consumption of drink in this area as high as possible We do not want to be continually reminded by expensive advertisements how thirsty we are, and we do want to be rid of the liquor influence in local politics" If that view prevailed a bare majority would turn the area into a reorganisation area and that meant that the whole of the manufacture and distribution of alcoholic liquor in that area would be managed by a central board of management assisted by central and local advisory committees They would get rid of redundant public-houses abolish grocers' licenses, do away with advertisements of liquor convert some public-houses according to local demands into places where food could be bought as well as drink, and secure that it was to nobody's interest that a large amount of drink should be consumed That meant disinterested management and followed the lines now prevailing in the Carlisle area The third option was called "no licence" There were a certain number of people in this country who believed that the only solution of their difficulties in regard to the liquor traffic was to abolish it altogether now Where that view prevailed not by a bare majority, but by a majority consisting of 55 per cent of the first preference votes, there would be no more licences at all Drink must not be sold or manufactured in that area, and if it was consumed there it must be by those who got it outside That was something very like prohibition, and here he quite recognised that they came up against one of the great difficulties of this Bill If they excluded that option they would certainly secure an amount of support in the country very much greater than that which the Bill had already secured But on the other hand, if they excluded that option they would also lose the support of many temperance societies and incur the active hostility of a few who would at once join the trade in opposing them They said that if they were going in for local option they had no right to rule out an opinion which was firmly held, whether rightly or wrongly, by a very considerable number of people just because other people happened to dislike it If they excluded the "no licence" option the Bill was wrecked, but he begged their lordships to remember that in speaking like this he was not arguing for prohibition, and also that the arguments against prohibition were not arguments against this Bill

Freedom in Revising Decisions

The Bill provided that areas should have a certain freedom in revising their decisions from time to time It was laid down in the Bill that the first polls should be taken three years after the Bill had been enacted, and the other polls four years later That was a doubtful point, and he did not think that they would lose very much if that requirement were dropped, and it was enacted that a fresh poll should be taken on the requisition of a certain number of voters However, the essential principle was that the polls were recurrent It was possible under this Bill for an area which had already decided to have periods of reorganisation to go forward, or as some might say backward, to prohibition On the other hand, an area which had had experience of a "no licence" period might come on reflection to desire that that should be modified If so, either could make the change, but neither of such areas having decided for reorganisation could go back to private ownership The last principle of the Bill was that during 15 years after its passing there should be compensation paid to all interested persons In the present Bill they had devised an easier and simpler scheme of valuation than that included in the 1924 Bill The new scheme of valuation was based on Section 20 of the Licensing Consolidation Act of 1910, and took market values as the standard both for valuation of licences and also for the valuation of bricks and mortar The Bill set up a Central Compensation Fund which was to be at the disposal of the Central Board of Management Into that fund came year by year, the trade levies The licensees would continue to pay as now, but the owners of tied houses (90 per cent of the whole) would pay an equivalent amount each year The compensation paid to owners of redundant houses under the Balfour Act of 1901 would cease This would result in a working capital which would come into the Compensation Fund at the rate of about £2,000,000 a year Unless the hopes of the prohibitionists in this matter were wildly exceeded, he thought that there was no chance of more areas going dry than could be comfortably managed by the finance of the Bill The Home Secretary had powers to postpone the second or third poll for a year if he found that the funds were not likely to be able to sustain the charges that might possibly be thrown upon them Further the Board of Management would be able under this Bill to borrow, with leave of the Home Secretary, upon security of their Compensation Fund, backed, if necessary, by the receipts of customs and excise He was not one of those who regarded the drink trade as a wicked trade or who regarded brewers and wine merchants and publicans as having bad consciences or no consciences at all The real wrong was that the trade should be left in a position which seemed to impose upon it an obligation so unwholesome and dangerous Forty years ago Lord Rosebery said "If the State does not control the liquor traffic the liquor traffic will control the State" He (the Bishop of Liverpool) saw the danger coming nearer and nearer Owing to the enormous influence wielded directly and indirectly by those who were concerned to uphold the liquor traffic they were approaching a state of things perilously near the corruption of our political system Sooner or later the country would have to tackle this question, and he did not think it could be solved unless they took the trade clean out of private hands altogether sold in this country will now, by virtue of the Therapeutic Substances Act, 1925, come under official control and have to conform to prescribed standards of potency and purity My right hon friend proposes to give some further consideration to the question, but it seems doubtful in view of the foregoing observations whether any departure from present practice would be justified

Dr Davies asked if Sir Kingsley Wood had seen the letter on this subject from Dr S Monckton Copeman, who was one of those who originally used "glycerinated lymph," which appeared in the *Times* that morning? Having in mind the prevalence of small-pox, would it not be possible *to see that Government lymph was sold to practitioners*

Sir Kingsley Wood said that there was no mention in the letter to the *Times* of the very *important* fact that under the Therapeutic Substances Act, which came into force in August, all lymph sold would have to come under official control and to conform to prescribed standards of potency and purity

Sir W Davison asked whether, having regard to the nature of an epidemic of small-pox, it would not be desirable to make some temporary arrangement until August to supply lymph to any practitioners who desired to have it.

Sir Kingsley Wood said that in all cases where there was an epidemic arrangements were made with the medical practitioners for the supply of Government lymph Under the Therapeutic Substances Act the natural desire which everyone shared that all lymph should be of the proper standard of efficiency would be achieved

Foot-and-Mouth Disease and Swiss Condensed Milk

Major Ainsworth asked the Minister of Health whether, in view of the existence of *foot-and-mouth* disease in Switzerland, he was satisfied that the large quantities of condensed milk imported into Great Britain from that country were free from contamination, and, if so how this deduction was formed —Mr Guinness replied I am informed that the process of condensing milk necessitates the maintenance for some time of temperatures which are sufficient to destroy the virus of foot-and-mouth disease

TUESDAY, MAY 31ST

Sickness in the Shanghai Defence Force

Mr Thurtle *asked the Secretary of State for War* the number of troops of the Shanghai defence force who had been admitted to hospital as a result of sickness *up to the* time of the latest report received by his department —Sir L Worthington-Evans replied I am unable to state the total number of admissions to hospital, but the average weekly number of officers and men of the Shanghai defence force and the permanent garrison at Hong Kong, including Indian troops, who were in hospital during the four weeks ending May 20th was *15 and 800 respectively*

Nervous Shock Caused by Motor Horns

Mr Pethick-Lawrence asked the Home Secretary whether he had received complaints as to cases of nervous shock caused by the unnecessary use of *strident* motor horns, and whether he proposed to take any action in the matter —Colonel Wilfrid Ashley replied I am aware that unnecessary noise is sometimes made by motor horns The point has been under consideration in *connexion* with the Draft Road Traffic Bill, but it seems to me more a question of education in the courtesies of the road than a matter for legislation, as it would obviously be extremely difficult to lay down a definite and enforceable standard of noise

Categories of Certified Milk

Mr Hurd asked the Minister of Health what was the number of licensed producers of graded milk, that was to say in the three categories of Certified, Grade A (T T) and Grade A respectively, the amount of the licence fee in each case and the total amount of such fees collected during the past year, and whether, *in view of the deterrent effect* of such fees upon the production of milk of guaranteed cleanliness, he would abolish these charges and regard *the work of the Ministry's* inspectors in this sphere as a public health service —Sir Kingsley Wood replied The numbers of licensed *producers* of Certified, Grade A (tuberculin tested), and Grade A milk in England and Wales on March 31st last were 121, 150, and (at least) 266 respectively The amount of the annual licence fee in each case is Certified, £5 Grade A (tuberculin tested) or Grade A, £1 1*s* (or if the milk is bottled on the farm, £3 3*s*) The total amount of the fees paid to my department in respect of *producers'* licences for Certified and Grade A (tuberculin tested) milk for the calendar year 1926 was £690 18*s* 6*d* Licences to to producers of Grade A *milk are* granted by local authorities and my right hon friend regrets that he cannot state either the precise number of such licences in operation or the total amount of fees paid in respect thereof My right hon friend has no reason to believe that the licence fees, which represent only a part of the cost of inspection and bacteriological examination, have had a deterrent effect on the production of clean milk and he does not at present propose to abolish them

Obituary.

BRYDEN GLENDINING, M S DURH., F R C S ENG

Mr Bryden Glendining, who died at his home at Aspley Guise on May 19th, was born at Dunedin, New Zealand, in 1880 and came to England when he was 18 years of age After five years' study at Guy's Hospital he graduated in medicine in the University of Durham in 1903 and was appointed house surgeon at Guy's Later he was appointed resident surgeon at the Hertford British Hospital in Paris, and on the marriage of the Queen of Spain, went with her to Madrid, where he remained as her medical attendant for about two years On his return to England Mr Glendining became pathologist to the Chelsea Hospital for Women He took the F.R C S diploma in 1908 and graduated as M S Durh in 1909 Two years later, whilst continuing work at the Chelsea Hospital, he became associated with the Cancer Research Laboratories of the Middlesex Hospital, where he was elected to an Emden Research Scholarship For the following account of his work at this time we are indebted to one of his colleagues —

"During his three years' tenure of this scholarship Glendining wrote no less than nine papers, nearly *all of which were on the subject of* malignant disease in its relation to gynæcology Perhaps the most important of these was one entitled the Spread of Carcinoma by the Fallopian Tube, in which he put forward an entirely new view as to the invasion of the Fallopian tube by carcinoma from the uterus and ovary He adduced evidence to show that it may be brought about 'by cancer cells which, coming in contact with the fimbriæ or being swept into the lumen engraft themselves upon the columnar cells, and thence travel to deeper parts' This conclusion is of special interest in view of the opinion now held by most pathologists that pelvic endometriomatosis is in many cases due to shifting of the epithelium lining the tubes or uterus. With the caution which characterised him, he saw that the possibility of lymphatic permeation from the ovarian growths could not be entirely excluded"

This research was carried out at a time when Glendining was actively engaged in gynæcological practice He was appointed assistant surgeon to the Chelsea Hospital and was also obstetric registrar to the Middlesex Hospital, in 1912 he became gynæcological surgeon to the Hampstead General Hospital His future seemed assured both as investigator and surgeon, but in the following year a breakdown in health made temporary retirement necessary In 1914, however, he returned to London to take up work again at the Chelsea and Hampstead Hospitals, *also* joining the surgical staff of the Duchess of Bedford's War Hospital at Woburn This *appointment* re-directed his attention to general surgery and in this field also he showed unusual ability, his clinical and operative skill being reinforced by a wide knowledge of pathological processes Apart from an interval of illness in 1916 he went on working at Woburn until 1925 The war hospital was closed in 1920 but Mr Glendining continued his association with the cottage hospital until failing health made complete retirement from practice necessary "The last years," we learn, "*were borne with a patience* and courage that nothing could dim The blow of 1913 was one from which he never really recovered physically, but it brought into high relief the fine qualities of the man The splendid work he did in the face of such a handicap will always be remembered by those who were in any way associated with him in it"

Mr Glendining leaves a widow, the daughter of Captain G E Hodgson, and one son

HOUSE OF COMMONS.

WEDNESDAY, MAY 25TH

Ventilation in Theatres and Public Halls

SIR **ROBERT THOMAS** asked the Minister of Health whether he was aware that there was neglect on the part of local authorities to ensure the provision of adequate means of ventilation in theatres, cinemas, and other places of public assembly, and whether he would appoint a committee to inquire into this matter.—Captain **HACKING** (Under Secretary for Home Affairs) replied: A circular was sent in 1920 to the licensing authorities urging them to use their powers under the Theatres Acts, 1843, to ensure the satisfactory condition of theatres, including ventilation. The Home Office have not received any complaints in recent years. If the hon. Member will send me any information he has in his possession, I will consider it.

Sale of Pasteurised Milk

Mr. **BUXTON** asked the Minister of Health the number of firms or persons licensed to sell pasteurised milk and the estimated proportion of pasteurised milk to other liquid milk sold in England and Wales.—Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied: The number of pasteurising establishments in England and Wales licensed on March 31st last was 120, and the number of other places licensed for the sale of pasteurised milk at the same date was 573. My right hon. friend has no definite figures as to the quantity of pasteurised milk *as defined by the Milk (Special Designations) Order*, sold in England and Wales, but it might be very provisionally put at between 5 and 10 per cent. of the total amount of liquid milk.

Death-rate among Miners

Mr. **SUTTON** asked the Minister of Health the general death-rate from all causes, and also the death-rate of miners from all causes for the country as a whole; and whether he could give such figures separately for the various mining areas.—Sir **KINGSLEY WOOD** replied: I may refer the hon. Member to the table (Table C) on page 326 of vol. 3 of the Report of the Royal Commission on the Coal Industry, 1925, containing the following statistics furnished by the Registrar-General of the deaths in standard populations at ages of coal miners in various mining localities:—

1921–23.

Locality.	Deaths—Coal miners in standard population aged 25–65.
Durham and Northumberland	665
Lancashire and Cheshire	760
Yorkshire West Riding	666
Derby and Nottingham	560
South Wales, including Monmouth	747

The corresponding figures for all England and Wales in 1921–3 are: all coal miners (aged 25–65), 673; all males (aged 25–65), 661.

Statutory Vaccination Declarations

Mr. **DAY** asked the Minister of Health if his attention had been called to the recent case of King *v.* Southwark Guardians *ex parte* Peabody Donation Fund, and if he was prepared to take steps to protect the interests of parents making the statutory declarations of belief that vaccination would be prejudicial to the health of their children by amending the Vaccination Orders of 1898 and 1907, so as to ensure that such statutory declarations should not be open to public inspection.—Mr. **CHAMBERLAIN** replied: The answer to the first part of the question is in the affirmative. As regards the second part, as the register required to be kept under the Vaccination Act of 1867 would still be open to inspection, it does not appear that the course suggested would serve any useful purpose.

THURSDAY, MAY 26TH

Government Housing Subsidy to the L.C.C.

Mr. **DAY** asked the Minister of Health what would be the approximate Government subsidy granted to the London County Council for housing schemes in the current year; and the number of houses it was proposed to erect under this subsidy scheme.—Sir **KINGSLEY WOOD** replied: The London County Council will receive the appropriate Exchequer contribution under the Housing Act, 1923, and the Housing (Financial Provisions) Act, 1924, for each house erected by them and by private enterprise with their assistance, and it is anticipated that about 9000 such houses will be completed during the financial year. In addition, it is expected that during the year about 900 tenement dwellings for rehousing in connexion with improvement schemes under the Housing Act, 1923, will be erected by the Council in respect of which the Exchequer contribution will be one-half of the estimated average annual loss incurred. It is estimated that the total payments to be made to the Council in the financial year 1927–28 on account of all housing schemes undertaken since 1919 (including schemes of the metropolitan boroughs under the Housing Act, 1919) will amount approximately to £570,000.

Small-pox in Northumberland

Mr. **RUSSELL** asked the Minister of Health whether his attention had been called to an outbreak of small-pox in Northumberland; the number of cases notified up to date and the areas chiefly affected; whether or not the epidemic was on the increase; whether he was satisfied that the local authorities had powers sufficient to cope with the position and that those powers were being exercised; and whether the source of infection had been traced.—Sir **KINGSLEY WOOD** replied: Small-pox has been prevalent in Northumberland since 1924. The total number of notified cases, up to the end of last week, is approximately 2300. The areas chiefly affected have been Ashington, Bedlingtonshire, Newcastle-on-Tyne, Morpeth, Prudhoe, and Tynemouth. The number of cases in the county shows no signs of diminution at present. My right hon. friend is of opinion that the local authorities have all necessary powers if adequate use is made by the public of the facilities provided for free vaccination, and is advised that these powers are being exercised. He is unable to state the original source of infection.

Condemned Houses in England and Wales

Mr. **DAY** asked the Minister of Health if he had any statistics showing the number of houses condemned for human habitation in England and Wales to the last convenient date; and if he could state the average number of *persons occupying those houses and the average number* of rooms contained in each house.—Mr. **CHAMBERLAIN** replied: According to the annual reports of medical officers of health for the year 1925, the latest date for which information is available, 14,035 houses were reported in that year as unfit for human habitation in England and Wales. Statistics are not available giving the further information desired by the hon. Member.

MONDAY, MAY 30TH

Evil Odour from Water in St. James's Park

Sir **WILLIAM DAVISON** asked the Home Secretary, as representing the First Commissioner of Works, whether his attention had been called to the evil odour at present arising from the ornamental water in St. James's Park which in some cases had caused sore-throats to those sitting by the water; and whether immediate steps would be taken to secure a remedy seeing that there was a large children's playground close to the lake.—Captain **HACKING** replied: Attention has already been drawn to this matter, and measures are being taken which it is hoped will provide an effective remedy.

Sir W. **DAVISON** asked if Captain Hacking was aware that the same thing occurred in 1910 and 1911 and that then it was successfully dealt with. Had the Office of Works considered whether the same treatment might not be carried out now?

Captain **HACKING** said that the Office of Works, in order to effect economy, had not run fresh water continuously into St. James's Park lake. The pumping of water from the Serpentine, however, was creating a current, which would probably have the desired effect.

Supply of Government Lymph to Private Practitioners

Sir **WILLIAM DAVISON** asked the Minister of Health whether he was aware that a number of the public were unwilling to go to public vaccinators to be vaccinated and preferred to be vaccinated by their own family doctor, though they desired to be vaccinated with Government lymph; that the Ministry were refusing to supply private practitioners other than public vaccinators with the lymph supplied by the Government lymph establishment, in which the public had confidence; and whether, having regard to the desirability, in the public interest, of having as few unprotected persons as possible, he would make arrangements for the supply of Government lymph to all qualified practitioners on application?

Dr. **VERNON DAVIES** asked the Minister of Health if he was aware that many medical practitioners, recognising the excellence of the lymph supplied to public vaccinators by the Government lymph establishment, would welcome the opportunity of purchasing supplies of this lymph for the vaccination of their private patients, but were precluded from doing so; and, bearing in mind the prevalence of small-pox in the country, would he consider the advisability of removing this restriction so that medical practitioners who were not public vaccinators might have the opportunity of using this lymph which had such a high reputation for efficiency.—Sir **KINGSLEY WOOD** replied: The reputation of Government lymph has been achieved, not only by its quality and consistency, but by the close attention given to its results by means of official inspection and records. If Government lymph were to be made available to private practitioners generally it would appear very difficult, if not impossible, to ensure similar checks and controls. Moreover, I may point out that as from August next, all vaccine lymph normal habits of life. The description I am now giving carries no reflection on these, but in the larger number of cases the patients have erred in two directions—too much intake and too little output. Many of them recall the type of persons so well described by the epitaph in the country churchyard as "a lady of bilious temperament and lazy habits of life."

The predisposing causes in the production of gall-stones are well described by Sir Humphry Rolleston. He points out that the most important are a sedentary life and want of exercise. Stones are rare in outdoor labourers; they occur in pet dogs, but are absent in wild animals; they affect hard-working literary men and prisoners confined to gaol. I have had several cases in prison attendants, which is eloquent testimony to the good feeding provided by the Government. Gall-stones are found more frequently amongst the rich, who are lazy, clerks and devoted men of business, shoemakers, and in the poor of workhouses and asylums, than in active persons, whether the well-to-do or tramps. At Carlsbad, of 472 patients under treatment for cholelithiasis, more than 50 per cent. were professors, teachers, officials, and clergymen.

The effect of famine conditions is well shown by statistics from a Leningrad hospital. In 1914 the incidence of gall-stones in the total admissions was 0.47 per cent.; in 1919 it had fallen to 0.1 per cent. Mr. E. P. Pratt has worked out for me the corresponding figures at St. George's Hospital. During the three years before the war the ratio of gall-stone cases to the total admissions was 1 case in 156 admissions; in the three years following the war the ratio was 1 in 148, a slight increase. An interesting point, however, is that patients below the age of 40 formed 26 per cent. of the total before the war, but only 11 per cent. after the war, which suggests that those who were active during the war did not readily form stones, and fits in with the fact that gall-stones are rare in soldiers. It is thus evident that the type of persons most liable to cholelithiasis are not the best of subjects for operations upon the upper part of the abdomen.

Operative Indications.

In view of the remarkable frequency of gall-stones it is evident that their mere presence is no indication for operation; obviously the great majority of those who own them get through life comfortably without ever being aware of their existence. It is sometimes asserted that gall-stones are never present without causing symptoms. This surely cannot be true, for if so there would be two or more millions of people in England alone suffering from symptoms due to gall-stones.

When it is remembered, too, that the majority of the patients are not good surgical subjects it is obvious that the question of operation must be carefully considered in each individual case. My contention is that any policy which urges that the diagnosis of gall-stones should be followed by operation, more or less as a routine, is wrong. The pros and cons should be considered in every case; the general health of the patient must be investigated very carefully, and the risk of future trouble in connexion with the stones should be estimated as far as possible. Often the best advice we can give to the patient is to undergo a full course of medical treatment during a period of observation. There will still remain, however, a very large number of cases in which operation is clearly the wiser course. This applies particularly to those subjects who are otherwise active and healthy; it applies to the cases in which there have been recurrent attacks of colic, severely handicapping the patient, and it applies to nearly all cases in which there have been stones in the ducts or some other complication, such as an acute infective cholecystitis.

Incidentally, the number of stones present has some influence on the need for operation, and some idea of the number may often be got from X ray photographs or from the size of any stones that are passed. A persons fated to have gall-stones would be wise, I think, if he had any choice in the matter, to have one large stone. Such stones are apt to lie comfortably in the gall-bladder; they cannot shift, and most often they are discovered accidentally. Large numbers of small stones give rise to little trouble, but some of them are apt to increase to a bothersome size. The troublesome size is that which leads to a tight fit in the ducts. When there are 20–30 stones in the gall-bladder they are likely to be of this size and then most often lead to acute troubles.

Gall-stones and Cancer.

The fact that gall-stones are often associated with cancer of the gall-bladder is sometimes held as an argument in favour of pressing operation. Hurst tells us that there are 4 millions of people with gall-stones in England; cancer of the gall-bladder is relatively an uncommon disease, so that it becomes clear that only a very small proportion of gall-stone patients develop carcinoma of the gall-bladder. Does this risk justify the 1 per cent. mortality risk of operation? Another point emerges from the study of series of cases—namely, that the majority of patients in whom stones accompany growth of the gall-bladder have had nothing in their previous history to point to gall-stones, and so prophylactic operations would not have been possible.

It is very difficult to get evidence on this point from statistics, for they vary so considerably. It seems quite clear that when carcinoma forms it is usually secondary to stones and that the stones found are not the result of the carcinoma. Stones occur in 90 per cent. of the cases of primary carcinoma and only in 15 per cent. of the cases of secondary carcinoma. In the London Hospital series of cases, Walton records 18 cases of carcinoma in 409 gall-stone cases; Smithers found 31 cases in 1000, whilst in the St. George's Hospital series there were 10 cases in 228, a percentage of 4.7. But it must be remembered that these figures represent the most serious of gall-bladder cases, and take no account of the innumerable patients who never enter hospital.

The risk of carcinoma scarcely seems to me great enough to warrant its use as a pressing argument for operation, and I find that when members of our own profession unluckily develop gall-stones, they are inclined to take this view when when deciding what shall be done for themselves.

Cholecystectomy.

Excision of the troublesome gall-bladder is an attractive operation; when the appendix is so easily dealt with by removal, why not treat the gall-bladder in the same way? But the matter is not so simple as that. Many of the patients are little suited for what is sometimes called surgical interference; they are often much too fat and flatulent, and liable to chest complications. Moreover, patients of this type are apt to keep their gall-bladders tucked away far back in the depths of their voluminous abdomens, and for some of these the simpler operation of cholecystostomy is much safer. In any case, excision cannot be done unless the surgeon has decided that the bile-ducts are surely patent.

There is another point in connexion with this operation which has a great influence on the ultimate result. The bed from which the gall-bladder is excised must be covered with peritoneum; if a raw surface is left, adhesions will form between the pyloric end of the stomach, or other neighbouring parts, and the under surface of the liver. In many a case the ultimate results of the operation have been unsatisfactory owing to these adhesions.

A practical difficulty is that patients often walk into one's consulting-room or into hospital and demand removal of their gall-bladders. A surgeon should never promise this; if he is old enough, he will never even promise to find gall-stones, whatever may have been the clinical signs and whatever the X rays may have shown. I have had several instances in which a complete investigation has led to a confident

INTER-STATE POST-GRADUATE ASSEMBLY OF NORTH AMERICA

VISIT TO LONDON, JUNE 1ST–3RD, 1927

INAUGURAL MEETING

ON Wednesday, June 1st, the Inter-State Post-Graduate Congress, which has its headquarters at Dartmouth House, Charles-street, Berkeley-square, commenced a three-day session, including lectures and visits to various London hospitals A large gathering attended the opening ceremony, which was performed by Lord Reading, P C, the chair being occupied by Lord Dawson of Penn

Lord DAWSON (chairman of the British Committee), in welcoming the delegates from oversea, paid a tribute to the organising ability of the secretary of the Congress, Mr Philip Franklin Such a congress as this one should advance knowledge and stimulate thought to the advantage of all the nations of the world After all, points of view in medicine were remarkably similar, and for medical men speaking the same language the exchange of ideas was a simple matter In these days the calling and the scope of medicine covered a wider range and was broader-based than formerly In years gone by the science was mainly concerned with the developed disease in the individual, whereas attention was nowadays largely devoted to what could be termed threshold symptoms, to that stage of deficient or dislocated function which was the precursor of actual disease states Hence doctors were being brought more and more into relationship with people still active who wished to maintain the best possible health, and hence more was now learned about people's lives and work This meant that the professional man was now in closer contact with national life, leading to a wider grasp of social problems and the establishment of a permanent and abiding influence on international relationships

As representing this wider purpose nothing could be more fitting than the presence of the Marquis of Reading, the chairman of the Executive Committee of the English-speaking Union Lord Dawson pointed out that few people had been privileged to serve in so many capacities as Lord Reading, enriching each by his learning, intuition, and sympathy Lawyer, statesman, judge, ambassador, viceroy—Lord Reading was truly a citizen of the world Lord Dawson concluded by promising that London medical circles would offer of their best to those who had come across the Atlantic

Lord READING said it was his privilege to extend, on behalf of the English-speaking Union, a very cordial welcome to the delegates to this Congress He was delighted, as always, to perform any function he could, especially one whose object was to secure an even closer relationship between the medical men of the two great countries, it must be, he was convinced, to the benefit of both He had heard that a man at 40 was either a fool or his own doctor, and he had often thought that he might be both Such a congress as this went even beyond the objects of the English-speaking Union, for, as it was true that science belonged to no particular nation, gatherings of this nature were really more than international; they belonged to the universe, seeing that all discoveries given to the profession were for the benefit of the whole of humanity A meeting of representatives of many States and of Canada with its resultant contacts here would, he hoped, help to strengthen the ties already existing between the two nations One of the strongest links in this association was provided by the unity of language spoken by all the participants in the congress Added to this was the fact that in both nations the tradition was the same He trusted, indeed he felt confident, that when the members of the congress returned to their own homes they would carry with them thoughts and recollections of this visit, and that whatever other countries their itinerary might include, they would still regard this country as the nearest to them, and imbue in others a like idea That would tend to strengthen still further what he regarded as the most important factor in the advance of human civilisation—namely, that the American and the British people should understand each other, and that they should, wherever possible, work for the common purpose of benefiting humanity

Dr W B PECK, on behalf of the American visitors, thanked Lord Reading and Lord Dawson for their words of welcome and the Union for its hospitality The Congress, he said, represented 38 States, and some practitioners from Canada were also present Medical men did not, as a body, usually interest themselves in State matters, and they were bad politicians at best, but it was a constant stimulus to the doctor to know that he had, in his work, the encouraging sympathy of those who were highly placed in the Government of the country In London they did not seem to be in a strange land, it was like coming back home

GALL-STONES

The opening Paper read at the First Session

BY SIR CRISP ENGLISH, K C M G, F R C S

OPINIONS about the treatment of gall-stones mainly differ on two questions (1) what are the indications for operation? and (2) should the diseased gall-bladder be excised, or should it be emptied and drained? To get a true perspective we must appreciate the remarkable frequency of gall-stones, and we must study the types of persons who manufacture them

The Frequency of Gall-stones

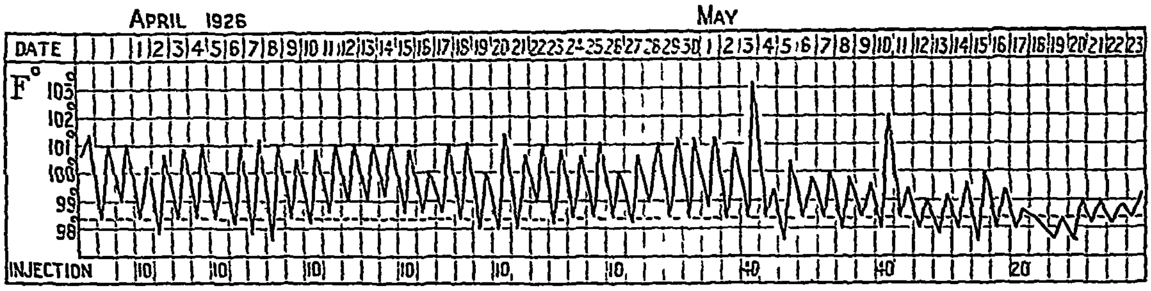
Their frequency is astonishing The available statistics vary considerably, but whatever allowances may be made, it is evident that quite a large percentage of any population possesses gall-stones Statistics taken from hospital post-mortem records put the percentage at from 3 to 15 when all ages are included, and a good deal higher if adults only are considered At St George's Hospital, in a series of over 4000 consecutive post-mortem examinations, gall-stones were found in 5 7 per cent The figures of last year were examined as regards autopsies on persons over 40 years of age, and stones were found in 10 per cent of the men and 25 per cent of the women, although in only one instance had the patient been admitted for gall-stone disease In series from other hospitals higher figures are often recorded, and it may be assumed that in better-class patients gall-stones are even commoner On the other hand, A J Walton, in a long series of post-mortem examinations at the London Hospital, found a percentage incidence of 3 48, a figure which is lower than most, and suggests that they are less frequent amongst the patients of the East End of London

Dr Arthur Hurst estimates that over 20 per cent of persons over the age of 20 have, or are going to have, gall-stones; that means 4 millions of people in this country, and a great many more in America Supposing that this is an over-estimate and there are only 2 millions, the number still remains remarkably high Of 100 people in this room, Hurst says that 20 have, or are going to have, stones Put it, if you will, at 10, the point that matters is that in all probability none of these has, or is going to have, symptoms In Piccadilly or Bond-street, where the well-favoured congregate, one person in every ten has gall-stones, but you will see no jaundice, you will not find any of them writhing in colic, you will get no evidence of flatulent dyspepsia Fortunately, stones, although so very common, are usually silent or latent, or the symptoms are so mild that they escape observation

Types of Patient.

Many of the gall-stone patients enjoy excellent health apart from their gall-bladder trouble and have a patient following only 10 c cm of serum He never rallied and died in a few weeks Compare this result with the first one I described where 40 c cm of the serum were used and the reactions followed by improvement In Case 2 the patient was doing badly until a sudden rupture of lung caused a violent reaction, after which he made an uninterrupted recovery. Yet I regard rupture of lung as one of the most serious complications of artificial pneumothorax Again, in Case 3, the patient seemed definitely to improve after pleural shock, but this accident, though fortunately very rare, is the one most dreaded in all cases where the pleura has to be punctured It is not only in tuberculosis that one sees improvement following shock During the war I treated several cases of enteric with colloidal gold given intravenously The patient generally had a rigor after the injection and the temperature would then fall to normal for a few days and sometimes would remain normal.

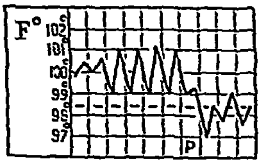
FIG. 1



Temperature chart in a case of pulmonary tuberculosis treated by injections of serum The figures at the bottom of the chart show the number of c cm of serum given on the various days

We know the effect of intravenous injections of mercuric chloride in cases of pneumonia or other acute infections It is quite impossible to believe that such a minute dose of the drug can have any direct effect on the micro-organisms Again, certain non-tuberculous conditions have been treated by shock produced by the intravenous injection of a foreign protein It would seem therefore that the action is largely non-specific and that a shock may stimulate certain unknown constituents of the body and do good or it may injure them and do harm

FIG 2



Temperature chart showing the effect of pleural shock occurring at P

FIG 3.

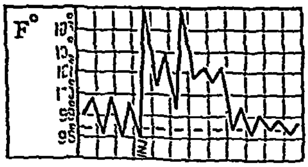


Chart showing the effect of an intravenous injection of 0 5 g sanocrysin

FIG 4

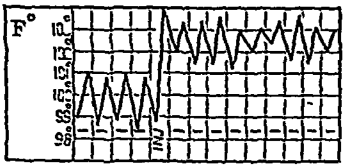

Chart showing the effect of an intramuscular injection of 10 c cm serum

In each one of the cases I have described the reaction was accidental and I was always alarmed at the time I believe that an acute flare-up may follow a reaction, and that this may be the beginning of a rapid spread of disease from which the patient soon succumbs Usually, however, he recovers from the reaction and is apparently neither worse nor better, but, as I have said, a considerable number of patients show a steady and continuous improvement after they have recovered from the initial shock.

Indications

When we consider these facts with a view to treatment we are at once faced with the difficulty that the reaction may make the patient worse or even prove fatal It certainly does not seem to me to be justifiable to cause such violent reactions as I have described intentionally, but I think that by small or graded doses mild reactions may be produced when other treatment has failed. In Case 1, for example, I gave six small doses of serum without any result, and as the patient seemed to be steadily dying I increased the dose and a reaction followed The temperature was definitely lowered, and it seemed to me wise to continue the serum in spite of the reaction I had of course, no intention of causing the serious shock which followed a subsequent injection

By causing a series of slight reactions I have occasionally seen improvement, though one does not see the striking and sudden improvement that may follow a serious shock. Usually the disease goes on unchecked in spite of the reactions. In children of 14 to 18 years of age one frequently sees a very acute form of pulmonary tuberculosis, and the outlook is always grave, but in these cases I have seen rapid improvement following reactions In such children the disease often spreads very quickly and I usually induce an artificial pneumothorax as soon as possible. If the disease is spreading in the other lung the pneumothorax cannot be kept up I have known cases where only two refills have been given when the treatment had to be stopped, yet steady improvement followed The very temporary and partial rest given to the lung can hardly account for the improvement, and I suggest that it is due to the shock or reaction caused by the pneumothorax. In severe acute cases I sometimes collapse one lung with a large initial quantity of air and give no refill but allow the lung to re-expand I have seen this method check the acute spread of the disease and be the starting-point of improvement

In treating patients by artificial pneumothorax I now give smaller refills than formerly, and I very rarely see a reaction Some years ago I might give as much as 800 or 1000 c cm of air as an initial dose. In those days reactions were frequent, but they were not uncommonly followed by a dramatic steadying of the temperature In another type of case the patient keeps fairly well in himself, but in spite of long periods of rest the temperature refuses to settle, remaining between 99°–100° F. and his condition shows no signs of improvement Now sometimes if the temperature is ignored and a little exercise is allowed the patient promptly begins to get better. In such cases I have seen the same result follow the use of tuberculin.

diagnosis of gall-stones and in which shadows have even been seen in the gall-bladder, yet at operation a healthy gall-bladder has been found of that delightful blue colour which we know spells innocence, and a chronic duodenal ulcer has been discovered to explain the symptoms instead The diagnosis between these two conditions is notoriously difficult and, in fact, sometimes they coexist, in these cases I believe that it is the duodenal ulcer which has been mainly responsible for the symptoms This impresses on one the very great importance of making a thorough examination of all the neighbouring parts, and especially of the stomach and duodenum, before the gall-bladder is attacked

There are some cases in which the wisdom of cholecystectomy will be doubtful after the usual thorough examination of the whole biliary system In cases of this type I am in the habit of doing an operation which is a compromise between cholecystectomy and cholecystostomy The gall-bladder with its contents can be removed at its junction with the cystic duct and then, instead of closing the duct, a drainage-tube can be put into it In this way the advantages of excision and drainage are combined, and the operation is often a much safer one than the ordinary excision and closure It involves a slight risk of leaving raw surfaces, and this part of the operation requires very careful attention

Broadly speaking cholecystectomy is the operation of election The absence of a gall-bladder brings no bad results R P Rowlands has reminded us that many animals are luckily born without gall-bladders and numerous human beings have lost it to enjoy better health Removal of the gall-bladder with the stones gives the best chance of permanent cure, it is often a simpler operation than drainage, its risk is usually no greater, and convalescence is much shorter The wounds heal quickly, whereas the drainage of cholecystostomy is often prolonged, the sinus taking some time to close The best plan is to keep an open mind before operation, and make no decision until the local conditions have been actually seen If the operator is in doubt, let him try to imagine what he would like done for his own gall-bladder if he were the patient

In conclusion, I would urge that there must be no hard-and-fast rules in our attitude towards gall-stones Stones are very common, often they give very little trouble, their owners are far from being ideal subjects for major surgery, so each case must have separate consideration If stones give rise to serious or repeated trouble, and if they are a definite handicap to the patient, then they should be dealt with, and cholecystectomy is the operation of choice

---

SHOCK TACTICS IN PULMONARY TUBERCULOSIS

By L S T Burrell, M D, F R C P

In cases of pulmonary tuberculosis a shock or reaction may be followed by disastrous results On the other hand, it may happen that the bad effects of the reaction soon disappear and the patient is actually better than he was before it occurred This improvement is not entirely the result of a specific effect I am not concerned in this paper with whether or not certain substances—for example, sanocrysin—have or have not a specific action, but I believe that in their action there is some other factor apart from anything specific Not only tuberculin, but also copper, gold, normal horse serum, T A B, &c, can set up a reaction which may be followed by a definite improvement or may cause a rapid spread of the disease A fall of temperature must not be taken as the sole index of improvement for it usually occurs in cases of shock, it is seen, for instance, in perforation in typhoid fever Certain drugs such as cryogenin will keep a temperature normal in pulmonary tuberculosis, but they do not affect the course of the disease.

Clinical Records

I will give a brief description of a few cases to illustrate improvement following reaction resulting from different causes.

Case 1 —A girl of 17 began to ail at the end of 1922, and in April, 1923, she had extensive signs of tuberculosis in the left lung, had lost 20 lb in weight, was febrile, and had sputum-containing tubercle bacilli in large numbers Left artificial pneumothorax was induced and a year later she was free from symptoms and had gained 52 lb in weight She kept well until the beginning of 1926, when after a febrile attack, which was at first thought to be influenza, signs were found in the right lung, tubercle bacilli reappeared in the sputum, and she was admitted to hospital with a temperature as shown in Fig 1

On April 1st, 1926, she was given an intramuscular *injection of 10 c cm of an antituberculous serum* which had been prepared by Capt S R Douglas The same dose was repeated on the 5th, 10th, 15th, 20th, and 26th with very little result. She was then extremely ill and wasted and apparently dying, so on May 3rd I gave 40 c cm of the serum which was followed by a big reaction and definite lowering of the temperature afterwards On May 10th I gave another 40 c cm of the serum and again there was a reaction as seen in the chart

On May 17th I was giving more serum and when 20 c cm had been injected she had anaphylaxis—that is to say, she suddenly collapsed, stopped breathing, became pulseless, lost control of her bladder and rectum, and appeared to be dead She recovered, however, and from that time she began steadily to improve The temperature became normal, the pulse-rate fell from 120 to 80, tubercle bacilli disappeared from the sputum, and at the end of the year she was in a sanatorium walking five miles a day

Case 2 —A man of 22 developed signs of pulmonary tuberculosis early in 1921, and at the end of the year went into a sanatorium He then had signs of disease all over the right lung, sputum loaded with tubercle bacilli, and an evening temperature of 102° F Right artificial pneumothorax was started in December, 1921, but he remained ill and febrile until May, 1922, when he had a sudden reaction with increase of fever and pleural effusion developed

The sudden nature of this reaction and the fact that the intrapleural pressure went at once from −6 to +8 suggests that a perforation of the lung had taken place Within a month not only did the effects of the reaction wear off, but the temperature became normal and his whole condition gradually improved and he left the sanatorium free from symptoms in May, 1923 The pneumothorax was kept up until May, 1924, and since then he has kept perfectly well Now, three years later, he is still free from symptoms and is leading a normal life

Case 3 —A woman of 26 with extensive signs in the right lung, tubercle bacilli in the sputum, temperature 101° F, and signs of toxæmia, was being treated by artificial pneumothorax. During the fifth refill, when 300 c cm of air had been introduced and the intrathoracic pressure was −6 +1, she suddenly became very cyanosed, gasped for breath, and lost consciousness She recovered in half an hour and afterwards began to improve Fig 2 shows the temperature In this case the improvement did not last long, she relapsed and died about a year later

Case 4 —A woman of 30 had active tuberculosis in both lungs, tubercle bacilli in the sputum, and fever, as seen in Fig 3 A severe reaction followed the intravenous injection of 0 5 g sanocrysin, but when she had got over this the temperature remained normal She steadily improved and lost the tubercle bacilli, but this may have been due to the rest in bed and the action of the sanocrysin which was continued in smaller doses Anyhow the fall in temperature did directly follow the reaction

Case 5 —A man had a tuberculous sinus from the transverse process of one of the vertebræ This showed no sign of healing in spite of prolonged treatment He was having mild sunlight treatment, and one day after an exposure to the sun, which was more than double the usual, he had a reaction and high temperature and felt that he had done himself harm But the sinus began to heal after this and has shown no sign of breaking down since

The Dangers of Shock

Dr R C Wingfield treated a series of cases with intravenous injections of colloidal copper He showed me his charts, and in some cases his results were strikingly good, but he found the reactions to be so severe and alarming to the patient that he discontinued the treatment

I started by saying that these reactions may lead to disastrous results, and Fig 4 shows the temperature of

Royal Sussex County Hospital—Mr Bernhard Baron has contributed £10,000 to the Centenary Fund of this hospital

Garden Fête at Guy's Hospital—On Thursday, June 9th, at 3 p m , the Lady Mayoress of London, accompanied by the Lord Mayor and sheriffs, will open a garden fête arranged by the Guy's Hospital Ladies' Association in the hospital grounds

Belgrave Hospital for Children—The report for 1926 of this institution in the Clapham-road, a new wing of which was opened by the Prince of Wales in March last, states that the out-patients' department with over 66,000 attendances is "lamentably overcrowded" This is 8000 more attendances than in 1924 and if the increase continues and more convenient premises are not obtained, "the point will soon be reached when sick children will have to be denied relief" The provision of additional departments has had the inevitable effect of considerably raising the cost of each in-patient A clinic has been established in the out-patients' department to which all fractures are referred, and it is hoped that much valuable information will thus be gained

A Year of St Bartholomew's Hospital—The treasurer, Lord Stanmore, reports an increase of in-patients last year from 8655 to 9233 , cases of street accidents or illness numbered 2972 The steady fall since 1920 in the attendances at the special treatment centre of the venereal department reflects the general reduction throughout the country of the incidence of the disease The cost per patient is, however, so much above the average of other venereal clinics that a scheme is under consideration for transferring the work to the hospital itself The League of St Bartholomew's Hospital Nurses, which now has 1200 members, is asking for the means to start a country club to which nurses and probationers can go for week-ends or longer periods

The late Dr J Busfield—Dr James Busfield, who died on May 19th at the age of 66, was a well-known Enfield practitioner who had practised in the district for more than 12 years He was a Yorkshireman by birth, and before taking up medical work was an analyst in the Inland Revenue Laboratories at Somerset House This appointment began in 1884, and in the following year he won first class honours and the bronze medal in technology at the City and Guilds Institute , he also became a Fellow of the Institute of Chemistry Later he entered Charing Cross Hospital Medical School without, however, giving up his work at Somerset House, which continued for ten years In 1890 he won the Pereira Prize and five silver medals at the hospital, and in the following year qualified as M R C S Eng Settling in practice at Clapham Park, Dr Busfield became medical officer to the Clapham General Dispensary, and later on, before going to Enfield, he was for some years in partnership at Claygate in Surrey At Enfield he took a keen interest in municipal and national politics, and since 1922 had represented the Enfield Western Division on the Middlesex County Council, serving on the mental hospitals and other committees At the time of his death he was president of the Enfield Medico Ethical Society and was a member of the staff of the War Memorial Hospital He was also president of the local tennis club Dr Busfield leaves a widow and two sons and a daughter

Bombay Medical Council—At the meeting of the Council held on Feb 25th, Sir Norman Walker, representative of the General Medical Council of Great Britain, and Colonel R A Needham, who accompanied him on his tour through India, were present by invitation — The case of Mr Balvantrai Naranji Desai, practising at Vadi Falia, Surat, was concluded, and it was decided that his name be struck off the Register for unprofessional conduct —viz , advertising—the purport of the advertisement in leaflet form being as follows "Remedy for cent per cent cure of Hydrocele By Balvantrai N Desai, L M S"—An application from Mr Narayan Moreshwar Bhagwat for permission to be registered under Section 7 (3) of the Bombay Medical Act, on the ground that he had been working as a medical practitioner for the past 17 years, was rejected as the applicant had not completed a course of training in any medical institution —An application from Shaikh Abdul Kadir was also considered, and taking into consideration the services rendered by him during the war and his training at the Grant Medical College, his application was favourably considered as a special case —The name of Muhammad Sahib Bakshubhai was erased from the Register owing to his conviction for a cognisable offence —A revised code of medical ethics was adopted, copies being forwarded to all registered medical practitioners for information and guidance —The meeting closed with a vote of thanks to the President, Major-General A Hooton, I M S , in view of his impending retirement before the next meeting

Woman Police Doctor—The Manchester Watch Committee has decided for the first time to appoint a woman doctor to a position in the city police force It will be her duty to deal with all women who come into contact with the police, and especially with all cases of assault on children, through the whole of the Manchester district

Holiday Cruise for Medical Men—The travel section of the *Bruxelles-Médical* has arranged a three weeks' course to Bordeaux, Lisbon, Tangier, Algiers, Palma, Barcelona, and Marseilles, starting from Le Havre on August 10th or from Antwerp Particulars may be obtained from Dr F G Imianitoff, M R C S, at 29, Boulevard Adolphe, Max, Brussels

Progress of West London Hospital—It was stated at the annual meeting last week that 1926 established a record in the number of patients dealt with—3135 in-patients and 43,417 new out-patients It is expected that the nurses' home will be extended during the year and a new casualty department is to be begun at the earliest possible moment During the last two years 76 beds have been added

The late Dr J T Haworth—At the age of 65, Dr John Thomas Haworth, of Filey, died on May 22nd after a short illness The son of a Filey doctor, he received his medical education at the University of Glasgow and took the Scottish triple diploma in 1888 At first in partnership with his father, he had an extensive practice in the neighbourhood and for the past 31 years had been medical officer of health for the Filey district of the Scarborough Union Dr Haworth was one of the oldest members of the local golf club, being at one time its captain, and was a prominent Freemason He leaves a widow and one son

A Curious Bargain—Some time ago Mr Alfred Ramsden, a retired Dewsbury draper, entered into an agreement with the Dewsbury Corporation that in return for £25 they would maintain and keep in good order three graves in one enclosure, with their monument and kerbs, in the consecrated portion of Dewsbury Cemetery Mr Ramsden has given £1000 to the Dewsbury and District Infirmary on condition that the board undertake in perpetuity to see, by periodical inspections, that the Corporation keep their agreement

Donations and Bequests—The late Mr Fenwick Richards, of Bristol, left, among other bequests, £1000 each to the National Lifeboat Institution, the Royal Bristol Hospital for Sick Women and Children, the Bristol Eye Hospital, the Orthopædic Hospital, Bristol, the Cancer Hospital, Brompton, the Consumption Hospital, Brompton, and the Bristol Dispensary, Castle Green —The late Mr Samuel Scott Stanley, of Grove House, North-lane, Roundhay, Leeds, in addition to other legacies, left £15,000 to Leeds Infirmary, £5000 to Leeds Dispensary, £2000 to the Leeds Women's and Children's Hospital, £1000 to the Society for the Prevention of Cruelty to Children, £1000 to the Society for the Prevention of Cruelty to Animals, and £500 to the Leeds Maternity Hospital

The late Dr W G Pinching—Dr William Guy Pinching, who died on May 16th, at the early age of 48, had practised in Frampton for the last 15 years He was educated at the University of Oxford and at Guy's Hospital, where he played regularly in the Rugby fifteen He qualified as M R C S Eng in 1908 and held the appointments of house physician and house surgeon at Guy's, afterwards going to Pendlebury as resident medical officer to the Manchester Children's Hospital At Frampton, Dr Pinching was identified with the cricket and football clubs and with many other social activities Amongst other local appointments he was medical officer of health for Wheatenhurst Union He leaves a widow and two children.

Royal Free Hospital—The 248 beds were last year occupied by 4729 patients, who stayed an average of 17 19 days and cost £4 6*s* 11*d* per week each, an increase of 1*s* 1*d* over the cost in 1925 The usual increases in the out-patients' and casualty departments are reported Eight beds in single rooms were allocated to private paying patients, and the arrangement has given satisfaction and produced considerable income The committee record with great regret the retirement of Dr W P S Branson, who had been physician to the hospital since 1908 , he has been elected a consulting physician Increased accommodation is badly needed, and it is proposed to celebrate the centenary of the hospital next year by erecting a children's wing, providing 30 or 40 rooms for private patients and more than a dozen other adjuncts upon the adjoining property, about an acre in extent, in Gray's Inn-road For these purposes £200,000 will be required

I want, however, to make it quite clear that I do not advocate exercise in febrile cases. On the contrary, I regard rest as far more important than anything else in the treatment of pulmonary tuberculosis A woman who was getting on very well left a sanatorium and was having what she called sanatorium treatment at home One afternoon she could not resist joining in a game of tennis This produced a severe reaction, and she died soon afterwards of acute tuberculosis I have seen many cases like this, and I know too well the danger of over-exertion in this disease I know too well the danger of any reaction, however caused, and I always do my utmost to avoid one in any case that is doing well But when one is faced with a patient who fails to respond to any treatment and who is steadily getting worse one cannot forget that a shock may turn the scale in favour of recovery, and rather than allow him to die I think it is right to try the effect of a slight reaction It should be done with the greatest caution and its risks should never be forgotten

Medical News.

UNIVERSITY OF OXFORD —The University has accepted with gratitude the sum of £1000 offered by the widow and sisters of the late Dr George Herbert Hunt for the purpose of establishing a medical travelling scholarship in memory of him

RONTGEN SOCIETY —A general meeting of this society will be held on Tuesday, June 14th, at 8 15 P M, in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, Cavendish-square, W 1 At 8 30 P M Sir J J Thomson, O M, F R S, will deliver the Tenth Silvanus Thompson Memorial Lecture, entitled the Structure of the Atom and Radiation —The Eighth Mackenzie Davidson Memorial Lecture will be delivered by Sir Humphry Rolleston at the same place on Thursday, June 30th, at 8 P M The subject will be Protection and other Radiological Problems Additional tickets for admission to the above lectures may be had from Mr Geoffrey Pearce, F R P S, 33, Newton-street, London, W C 2

UNIVERSITY COLLEGE, DUBLIN —The vacancies left on the staff of the College by the death in 1925 of Dr E J McWeeney, professor of pathology and bacteriology, and by the resignation, in the same year, of Dr J F O'Carroll, professor of medicine, have now been filled In each case the duties of the chair are divided Mr T T O'Farrell is appointed Professor of Pathology, Dr W D O'Kelly, Professor of Public Health and Bacteriology, Dr Henry F Moore, Professor of Medicine, and Dr James N Meenan, Professor of Systemic Medicine

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —Mr T W Letchworth will give a special clinical demonstration at the Royal Eye Hospital on Thursday, June 9th, at 3 P M This demonstration will be free to members of the medical profession The Chelsea Hospital for Women will hold a two weeks' course in gynæcology from June 8th to 21st, instruction will be by operation and by lectures (fee £5 5s) From June 8th to 29th an afternoon course will be provided at the Central London Ophthalmic Hospital, with lecture-demonstrations and instruction in the out-patient department An operative class will be arranged if desired—the fees being £3 3s for the clinical course and £5 5s for the operative course The Children's Clinic, in conjunction with several hospitals, will give a special course in diseases of children from June 13th to 25th (fee £2 2s) The Hospital for Diseases of the Skin, Blackfriars, will hold an afternoon course from June 20th to July 1st, on each Tuesday special cases of interest will be shown From June 27th to July 9th there will be a course at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, during which the entire practice of the hospital will be open (fee £2 2s) Practical courses in anæsthetics and obstetrics can be arranged for by the Fellowship, which also makes arrangements for clinical assistantships in gynæcology A general course of instruction is also provided at the associated hospitals for which a separate programme is published Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

SIR James Purves-Stewart has been elected a foreign member of the Copenhagen Medical Society

RADIUM INSTITUTE, MANCHESTER —At the annual meeting of the Manchester and District Radium Institute it was reported that the number of attendances had increased to 6775 from 6479 the previous year Longer treatment had been employed in certain types of cases There are now 11 beds for in-patients in the institute

THE medico-educational monthly journal, *The Child*, founded in 1910 and edited for nearly 17 years by Dr T N Kelynack will, after the issue of the June number, be conducted under the direction of an editorial board It will be published, as before, by Messrs John Bale, Sons and Danielsson.

INTERNATIONAL POST-GRADUATE COURSE AT CARLSBAD —A course having special reference to balneology will be held at Carlsbad from Sept 18th to 24th It is stated that Prof H H Dale, F R S, will give a lecture on the Theory of the Action of Insulin The course is open to all medical practitioners, and a Czecho-Slovakian visa will be supplied without charge and a 33 per cent reduction allowed on the State railways Further information may be had from Dr Edgar Ganz, Carlsbad

METROPOLITAN HOSPITAL SUNDAY FUND —At a reception held at the Mansion House on May 31st Mr Holland Martin referred to the decreasing amounts received from the annual collection on Hospital Sunday During the war the public had become accustomed to giving large sums to hospitals in the war area, and their charity was afterwards transferred to the London hospitals Between 1920 and 1926, however, the receipts fell from £121,000 to £87,000 Sir George Makins, F R C S, chairman of the distribution committee, stated that almost the whole of the money collected went to the hospitals

HOSPITAL PATIENTS AND NOISES —Some time ago the cinemas in Leicester were asked to screen requests to motorists not to use their hooters unnecessarily when passing the Royal Infirmary A private hospital in that city has just adopted a method of its own in the hope of reducing the noise of traffic upon its front where there chances to be a steep gradient White lines have been painted on the road at each corner of the building and large white boards have been placed on the walls with the words "speed limit, 8 miles," painted in bright red letters

ASSOCIATION OF PORT SANITARY AUTHORITIES —In recognition of his services as founder and hon secretary of this association since its inception in 1898, Dr J Wright Mason, of Hull, was entertained at a complimentary luncheon at the Charing Cross Hotel on May 27th After the President (Councillor J E Jones, of Bristol), Dr W M Willoughby and others had eulogised Dr Mason's work on behalf of those engaged in port health administration, Alderman Clough (River Tyne P S A) presented the guest of honour with an inscribed silver salver and a cheque which had been subscribed for by members of the association After gratefully acknowledging the presentation, Dr Mason gave an interesting account of the beginnings of the association and the useful work it has since accomplished Nearly every port medical officer was present at this luncheon to their senior colleague

BIRMINGHAM HOSPITAL CENTRE —As we recently recorded, the committee charged with laying out the site for the new Birmingham Hospital Centre at Edgbaston appointed a deputation to visit a number of continental hospitals, in order to form an opinion upon the relative advantages of the pavilion plan and of a large concentrated building The deputation consisted of Dr J G Emanuel, Mr J B Leathes, Mr H H Sampson, and Mr A H Leaney, and visits were paid to Rome, Genoa, Naples, Lyons, Paris, Hamburg, Copenhagen, Leipzig, Berlin, and Helsingborg in Sweden It was found that in most places the hospitals were built on the pavilion system, the pavilions usually being widely separated and therefore occupying a large area At Copenhagen, however, it has been decided to abandon this system owing to the heavy cost of administration, and the deputation report that "all authorities agree that the system of pavilions spread over a large area is costly to build and to heat, and very expensive to administer" Wherever they went they found hospitals to contain from 1000 to 3000 beds being built from 3 to 5 miles away from the centre of the city, though the out-patients' departments remained urban Most wards were badly overcrowded, there were more medical than surgical beds, and "in no case was the work anything like so intensive as in the Birmingham voluntary hospitals"

ROYAL SUSSEX COUNTY HOSPITAL —Mr Bernhard Baron has contributed £10,000 to the Centenary Fund of this hospital.

GARDEN FÊTE AT GUY'S HOSPITAL —On Thursday, June 9th, at 3 P M., the Lady Mayoress of London, accompanied by the Lord Mayor and sheriffs, will open a garden fête arranged by the Guy's Hospital Ladies' Association in the hospital grounds

BELGRAVE HOSPITAL FOR CHILDREN —The report for 1926 of this institution in the Clapham-road, a new wing of which was opened by the Prince of Wales in March last, states that the out-patients' department with over 66,000 attendances is "lamentably overcrowded" This is 8000 more attendances than in 1924 and if the increase continues and more convenient premises are not obtained, "the point will soon be reached when sick children will have to be denied relief" The provision of additional departments has had the inevitable effect of considerably raising the cost of each in-patient A clinic has been established in the out-patients' department to which all fractures are referred, and it is hoped that much valuable information will thus be gained

A YEAR OF ST BARTHOLOMEW'S HOSPITAL —The treasurer, Lord Stanmore, reports an increase of in-patients last year from 8655 to 9233, cases of street accidents or illness numbered 2972 The steady fall since 1920 in the attendances at the special treatment centre of the venereal department reflects the general reduction throughout the country of the incidence of the disease The cost per patient is, however, so much above the average of other venereal clinics that a scheme is under consideration for transferring the work to the hospital itself The League of St Bartholomew's Hospital Nurses, which now has 1200 members, is asking for the means to start a country club to which nurses and probationers can go for week-ends or longer periods

THE LATE DR J BUSFIELD —Dr James Busfield, who died on May 19th at the age of 66, was a well-known Enfield practitioner who had practised in the district for more than 12 years He was a Yorkshireman by birth, and before taking up medical work was an analyst in the Inland Revenue Laboratories at Somerset House This appointment began in 1884, and in the following year he won first class honours and the bronze medal in technology at the City and Guilds Institute, he also became a Fellow of the Institute of Chemistry Later he entered Charing Cross Hospital Medical School without, however, giving up his work at Somerset House, which continued for ten years In 1890 he won the Pereira Prize and five silver medals at the hospital, and in the following year qualified as M R C S Eng Settling in practice at Clapham Park, Dr Busfield became medical officer to the Clapham General Dispensary, and later on, before going to Enfield, he was for some years in partnership at Claygate in Surrey At Enfield he took a keen interest in municipal and national politics, and since 1922 had represented the Enfield Western Division on the Middlesex County Council, serving on the mental hospitals and other committees At the time of his death he was president of the Enfield Medico Ethical Society and was a member of the staff of the War Memorial Hospital He was also president of the local tennis club Dr Busfield leaves a widow and two sons and a daughter

BOMBAY MEDICAL COUNCIL —At the meeting of the Council held on Feb 25th, Sir Norman Walker, representative of the General Medical Council of Great Britain, and Colonel R A Needham, who accompanied him on his tour through India, were present by invitation —The case of Mr Balvantrai Naranji Desai, practising at Vadi Falia, Surat, was concluded, and it was decided that his name be struck off the Register for unprofessional conduct —viz, advertising—the purport of the advertisement in leaflet form being as follows "Remedy for cent per cent cure of Hydrocele By Balvantrai N Desai, L M S"—An application from Mr Narayan Moreshwar Bhagwat for permission to be registered under Section 7 (3) of the Bombay Medical Act, on the ground that he had been working as a medical practitioner for the past 17 years, was rejected as the applicant had not completed a course of training in any medical institution —An application from Shaikh Abdul Kadir was also considered, and taking into consideration the services rendered by him during the war and his training at the Grant Medical College, his application was favourably considered as a special case —The name of Muhammad Sahib Bakshubhai was erased from the Register owing to his conviction for a cognisable offence —A revised code of medical ethics was adopted, copies being forwarded to all registered medical practitioners for information and guidance —The meeting closed with a vote of thanks to the President, Major-General A Hooton, I M S, in view of his impending retirement before the next meeting

WOMAN POLICE DOCTOR —The Manchester Watch Committee has decided for the first time to appoint a woman doctor to a position in the city police force It will be her duty to deal with all women who come into contact with the police, and especially with all cases of assault on children, through the whole of the Manchester district

HOLIDAY CRUISE FOR MEDICAL MEN —The travel section of the *Bruxelles-Médical* has arranged a three weeks' course to Bordeaux, Lisbon, Tangier, Algiers, Palma, Barcelona, and Marseilles, starting from Le Havre on August 10th or from Antwerp Particulars may be obtained from Dr F G Imianitoff, M R C S, at 29, Boulevard Adolphe, Max, Brussels

PROGRESS OF WEST LONDON HOSPITAL —It was stated at the annual meeting last week that 1926 established a record in the number of patients dealt with—3135 in-patients and 43,417 new out-patients It is expected that the nurses' home will be extended during the year and a new casualty department is to be begun at the earliest possible moment During the last two years 76 beds have been added

THE LATE DR J T HAWORTH —At the age of 65, Dr John Thomas Haworth, of Filey, died on May 22nd after a short illness The son of a Filey doctor he received his medical education at the University of Glasgow and took the Scottish triple diploma in 1888 At first in partnership with his father, he had an extensive practice in the neighbourhood and for the past 31 years had been medical officer of health for the Filey district of the Scarborough Union Dr Haworth was one of the oldest members of the local golf club, being at one time its captain, and was a prominent Freemason He leaves a widow and one son

A CURIOUS BARGAIN —Some time ago Mr Alfred Ramsden, a retired Dewsbury draper, entered into an agreement with the Dewsbury Corporation that in return for £25 they would maintain and keep in good order three graves in one enclosure, with their monument and kerbs, in the consecrated portion of Dewsbury Cemetery Mr Ramsden has given £1000 to the Dewsbury and District Infirmary on condition that the board undertake in perpetuity to see, by periodical inspections, that the Corporation keep their agreement

DONATIONS AND BEQUESTS —The late Mr Fenwick Richards, of Bristol, left, among other bequests, £1000 each to the National Lifeboat Institution, the Royal Bristol Hospital for Sick Women and Children, the Bristol Eye Hospital, the Orthopædic Hospital, Bristol, the Cancer Hospital, Brompton, the Consumption Hospital, Brompton, and the Bristol Dispensary, Castle Green —The late Mr Samuel Scott Stanley, of Grove House, North-lane, Roundhay, Leeds, in addition to other legacies, left £15,000 to Leeds Infirmary, £5000 to Leeds Dispensary, £2000 to the Leeds Women's and Children's Hospital, £1000 to the Society for the Prevention of Cruelty to Children, £1000 to the Society for the Prevention of Cruelty to Animals, and £500 to the Leeds Maternity Hospital

THE LATE DR W G PINCHING —Dr William Guy Pinching, who died on May 16th, at the early age of 48, had practised in Frampton for the last 15 years He was educated at the University of Oxford and at Guy's Hospital, where he played regularly in the Rugby fifteen He qualified as M R C S Eng in 1908 and held the appointments of house physician and house surgeon at Guy's, afterwards going to Pendlebury as resident medical officer to the Manchester Children's Hospital At Frampton, Dr Pinching was identified with the cricket and football clubs and with many other social activities Amongst other local appointments he was medical officer of health for Wheatenhurst Union He leaves a widow and two children

ROYAL FREE HOSPITAL —The 248 beds were last year occupied by 4729 patients, who stayed an average of 17 19 days and cost £4 6*s* 11*d* per week each, an increase of 1*s* 1*d* over the cost in 1925 The usual increases in the out-patients' and casualty departments are reported Eight beds in single rooms were allocated to private paying patients, and the arrangement has given satisfaction and produced considerable income The committee record with great regret the retirement of Dr W P S Branson, who had been physician to the hospital since 1908, he has been elected a consulting physician. Increased accommodation is badly needed, and it is proposed to celebrate the centenary of the hospital next year by erecting a children's wing, providing 30 or 40 rooms for private patients and more than a dozen other adjuncts upon the adjoining property, about an acre in extent, in Gray's Inn-road For these purposes £200,000 will be required

I want, however, to make it quite clear that I do not advocate exercise in febrile cases On the contrary, I regard rest as far more important than anything else in the treatment of pulmonary tuberculosis A woman who was getting on very well left a sanatorium and was having what she called sanatorium treatment at home. One afternoon she could not resist joining in a game of tennis This produced a severe reaction, and she died soon afterwards of acute tuberculosis I have seen many cases like this, and I know too well the danger of over-exertion in this disease I know too well the danger of any reaction, however caused, and I always do my utmost to avoid one in any case that is doing well But when one is faced with a patient who fails to respond to any treatment and who is steadily getting worse one cannot forget that a shock may turn the scale in favour of recovery, and rather than allow him to die I think it is right to try the effect of a slight reaction It should be done with the greatest caution and its risks should never be forgotten.

ASSOCIATION OF PORT SANITARY AUTHORITIES —In recognition of his services as founder and hon secretary of this association since its inception in 1898, Dr J Wright Mason, of Hull, was entertained at a complimentary luncheon at the Charing Cross Hotel on May 27th After the President (Councillor J E Jones, of Bristol), Dr W M Willoughby and others had eulogised Dr Mason's work on behalf of those engaged in port health administration, Alderman Clough (River Tyne P S A) presented the guest of honour with an inscribed silver salver and a cheque which had been subscribed for by members of the association After gratefully acknowledging the presentation, Dr Mason gave an interesting account of the beginnings of the association and the useful work it has since accomplished Nearly every port medical officer was present at this luncheon to their senior colleague

BIRMINGHAM HOSPITAL CENTRE —As we recently recorded, the committee charged with laying out the site for the new Birmingham Hospital Centre at Edgbaston appointed a deputation to visit a number of continental hospitals, in order to form an opinion upon the relative advantages of the pavilion plan and of a large concentrated building The deputation consisted of Dr J G Emanuel, Mr J B Leathes, Mr H H Sampson, and Mr A H Leaney, and visits were paid to Rome, Genoa, Naples Lyons, Paris, Hamburg, Copenhagen, Leipzig, Berlin, and Helsingborg in Sweden It was found that in most places the hospitals were built on the pavilion system, the pavilions usually being widely separated and therefore occupying a large area At Copenhagen, however, it has been decided to abandon this system owing to the heavy cost of administration, and the deputation report that "all authorities agree that the system of pavilions spread over a large area is costly to build and to heat, and very expensive to administer" Wherever they went they found hospitals to contain from 1000 to 3000 beds being built from 3 to 5 miles away from the centre of the city, though the out-patients' departments remained urban Most wards were badly overcrowded, there were more medical than surgical beds, and "in no case was the work anything like so intensive as in the Birmingham voluntary hospitals"

St Peter's Hospital for Stone, &c , Henrietta street, Covent garden, W C—Clin Assts
Seamen's Hospital Society, Dreadnought Hospital, Greenwich—Anæsthetist. 50 guineas Also H P and H S At rate of £110
Sheffield Royal Infirmary—H S At rate of £80
Stafford, Staffordshire General Infirmary—H S At rate of £200
Southampton County (Mental Deficiency Act, 1913)—Med Adviser £700
University College Hospital, Gower-street, W C—Surg Reg £250
University of London—University Chair of Pathology £1000 External Examinerships Also Laura De Saliceto Studentship £150
Victoria Hospital for Children, Tite-street, Chelsea, S W—Sen Res M O £250
Warwickshire, King Edward VII Memorial Sanatorium, Hertford Hill, near Warwick—Asst Res M O £350
West London Hospital, Hammersmith road, W—H P and H S Each at rate of £100
Willesden General Hospital, Harlesden-road, N W—Hon Surg to Ear, Nose, and Throat Dept Also Clin Assts to Out patients
Wolverhampton and Staffordshire Hospital—H S At rate of £150 Res Surg O £250
Worksop, Victoria Hospital—H S At rate of £170

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Cottingham, Northamptonshire

Births, Marriages, and Deaths.

BIRTHS.

Ainscow—On May 22nd, at Hagley road, Birmingham, the wife of Dr J Arthur Ainscow, of a daughter

Canning—On May 26th, the wife of Dr H G R Canning, of Wimpole street, of a son

Osborne—On May 26th, at Ciola, Watford, the wife of Denis C Osborne, M B , Ch B , of a son

Smith—On May 27th, at 5, Cavendish-terrace, Stanwix, Carlisle, to Gwendoline (née Chave), wife of Dr J N Douglas Smith—a son

Wilson—On May 13th, at Bushey Heath, the wife of Dr E A Wilson, of a son

MARRIAGES.

Hodges—Legg—On May 26th, at St Mary Magdalene, South Bersted, Bognor, Lt -Col Aubrey D P Hodges, C M G , M D , late P M O , of Uganda Protectorate, to Hilda Margaret, youngest daughter of the late Rev F S Legg, M.A , formerly vicar of Christ Church, Mitcham, and late rector of Alfold, Surrey

DEATHS

Brodribb—On May 27th, at The Field, Penmaenmawr, N Wales, Charles Hildred Brodribb, M B , B S , Major, I M S (retd)

Coffin—On May 27th, at Carlton-vale, N W , Richard James Maitland Coffin, F R C P , Hon Assoc Order of St John of Jerusalem, Major (late R A.M C T), in his 85th year

Gibbs—On May 21st, at Caple gardens St Leonards-on-Sea, suddenly, Herbert J Gibbs, M.R C.S , L R C P Lond (late Medical Service, Singapore), aged 64

Glendining—On May 19th, at Aspley Guise, Bedfordshire, Bryden Glendining, F R.C S

Griffith—On May 21st, at the Caernarvon Cottage Hospital, following an operation Richard Griffith, M R C S , J P , late Major, 6th R W F , Lieut -Colonel, R A M C , of Penclogwyn, Portmadock, aged 53

Lacy—On May 19th, at Saumerez, Sunninghill, Alexander Gairdner Lacy, M D

Robinson—On May 25th, 1927, at 45b, Golders Green road N W 11 Isabel Kate, aged 72, widow of Dr Arthur H Robinson of St Mary's Infirmary, Highgate-hill

Smith—On May 24th at Bandrum Carnock, Fife, James Burnett Smith, M B , C M Edin , in his 70th year

Tay—On May 15th, at Lyndhurst, Oakhill road, Croydon, Waren Tay, F R C S , in his 84th year

N B—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

---

Osteopaths and the Medical Act.—In an annotation in The Lancet last week (May 28th, p 1143) it was stated that the deputy county court judge sitting at Marylebone had made a certain decision dealing with the right of an osteopath to recover fees We are reminded that the case was not, in fact, heard at Marylebone, but by the deputy county court judge sitting at Bloomsbury, as was stated in the report published in The Lancet of March 5th (p 510)

Notes, Comments, and Abstracts.

MEDICAL RELIEF IN RURAL INDIA.

(Being part of a Report to the Government of Bombay)

By Major-General Alfred Hooton, C I E , M R C S ,

ACTING DIRECTOR GENERAL, INDIAN MEDICAL SERVICE.

The demand for medical aid in rural areas is becoming more and more insistent The regular practitioners, fully qualified on modern scientific lines, are too expensive to be multiplied indefinitely for country work, and Government and the local authorities can only hope to keep a moderate number of them established in institutions, designed primarily to serve the poorer population of comparatively large centres and to deal with Government and municipal duties Apart from these, it is evident that some less expensive agency must be found for the villages and rural areas in general

Broadly speaking, the alternatives to the regular practitioners are the vaid or hakim, who in many cases is already available on the spot, and the possibility of creating some inferior class of whole-time or part-time practitioner, trained, in however elementary a manner, on modern scientific lines The question of choice is a most important one, involving as it does the future medical progress of India, and it is worth while to consider carefully the arguments for and against each alternative before committing ourselves to steps which it would be difficult or even perhaps impossible to retrace

The Indigenous Systems of Medicine

The attempts which have occasionally been made to brush aside the Ayurvedic and Unani systems of medicine with contempt may be at once rejected The former, at all events, can claim some of the most eminent pioneers of the profession, and it is certain that 500 years ago both the Hindu and Mohammedan physicians must have been greatly superior in many respects to those of Europe The names of Charaka and Sushruta may fairly be placed beside those of Hippocrates and the other ancient Greek physicians, and in point of time they preceded them The Ayurvedic school laid the foundations of modern anatomy, physiology, and pathology, and also discovered many useful drugs

But though the researches of the practitioners of the ancient Indian systems were most enterprising and praiseworthy, considering the conditions under which they were made, the absence of modern facilities led them into many errors Thus, although the vaids dissected bodies, it was by such crude methods that they confused arteries with tendons, and tendons with nerves, and although they recognised and described the main organs they had no accurate knowledge of their functions The theory of pathology which they evolved was merely speculative, and it is only by an entirely unjustifiable stretch of the imagination that the humours—*vat* (wind), *pitta* (bile), and *kapha* (phlegm)—can be made to fit into any reasonable scheme of modern pathology. The remedies they employed, moreover, were on an entirely empirical footing, and the doses were not properly worked out, so that when powerful drugs were used considerable risks of over-dosage were often run At the present day it is not uncommon to come across instances of such dangers Mercury is perhaps the most familiar example, and cases of necrosis and sometimes total loss of the lower jaw from excessive doses administered by practitioners of the indigenous systems are only too frequent Arsenic is also given by them, and gastro-intestinal irritation from its improper use is not unknown Inability to recognise conditions under which certain drugs cannot safely be administered is also a frequent cause of danger for men who have had no regular scientific training, and two cases may be quoted which appeared in the press last year · one, presumably of intestinal obstruction, in which a large dose of croton oil was given improperly by a hakim, and another of asthma, in which some unknown drug was administered In both death was reported to have followed almost immediately It has also to be added that practitioners of the indigenous systems keep their remedies secret, when they are able to do so, thus making research difficult and limiting the spread of knowledge

Modern Scientific Medicine

The system of medicine commonly spoken of as Western Medical Science is not a product of purely European growth Like astronomy and some other sciences it had its origin, not in the West, but in the East, and it is the result of the impact of modern scientific thought—mainly, no doubt, a Western development—on the ancient knowledge At the present time the modern system incorporates many of

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole street, W.

THURSDAY, June 9th.—LARYNGOLOGY AND OTOLOGY. Combined Summer Meeting. Laryngological Session at 2.30 P.M. *Papers*: Mr. F. Bradshaw Gillespy: Chronic Hyperplasia of the Upper Jaw. Mr. Walter G. Howarth: Some Points in the Technique of Laryngo-fissure. Mr. T. B. Layton: The Relation of Nasal Polypi to Inflammation of Accessory Sinuses of the Nose. Mr. Douglas Guthrie and Mr. Norman Dott: On the Occurrence of Brain Tissue in the Nose, the so called Nasal Glioma.

FRIDAY.—LARYNGOLOGY AND OTOLOGY. Combined Summer Meeting. Otological Session from 10 A.M. to 12.30 P.M. *Papers* on Progressive Middle-ear Deafness by Dr. Scott Williamson and Mr. E. Horace Richards, Mr. G. J. Jenkins, and Dr. Dan McKenzie. Demonstration: Dr. Graham Hodgson (introduced by Mr. G. J. Jenkins and Mr. F. W. Watkyn-Thomas): Some Radiograms of the Normal and Abnormal Labyrinth. *Paper*: Dr. Dan McKenzie: Posterior (mastoid) Drainage in Acute Suppuration of the Middle Ear. Laryngological Clinical Meeting at 4 P.M. Cases and Specimens will be shown by Mr. W. S. Syme, Mr. Harold Kisch, Mr. T. B. Layton, and others. 8.30 P.M., OPHTHALMOLOGY (Cases at 8 P.M.). Demonstration: Lieut.-Colonel H. Herbert: Photomicrograph Demonstration of the Anatomy of the Filtration Angle. Annual General Meeting. Election of Officers and Council.

SATURDAY.—LARYNGOLOGY AND OTOLOGY. Combined Summer Meeting (contd.). Otological Session (Clinical Meeting) at 10 A.M. (Cases at 9.30 A.M.). *Paper* (with Cinematograph Demonstration): Dr. Georges Portmann (Bordeaux): The Saccus Endolymphaticus and an Operation for Draining the Same for the Relief of Vertigo. Demonstration: Dr. Albert Gray: Stereoscopic Transparencies of Specimens of the Temporal Bone. Cases and Specimens will be shown by Dr. A. R. *Friel*, Mr. A. R. *Tweedie*, Dr. T. B. Jobson, Mr. Norman Barnett, Mr. E. Broughton Barnes, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W. 1.

MONDAY, June 6th, to SATURDAY, June 11th.—FELLOWSHIP OF MEDICINE, Thurs., 3 P.M., Special Clinical demonstration at the Royal Eye Hospital by Mr. T. W. Letchworth. *Free to members of the medical profession.*—CHELSEA HOSPITAL FOR WOMEN, Arthur street, S.W. Special course in Gynecology. Mornings and/or afternoons.—CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd street, W.C. Afternoon course. Lecture demonstrations and instruction in the O.P. Department.

Further information from the Secretary.

SOUTH-WEST LONDON MEDICAL SOCIETY. BOLINGBROKE LECTURE.

WEDNESDAY, June 8th.—9 P.M. (*in the Bolingbroke Hospital, Bolingbroke Grove, Wandsworth Common, S.W. 11*), Mr. W. McAdam Eccles: The Romance of Fœtal Pathology. Open to any member of the medical profession.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

THURSDAY, June 9th.—5 P.M., Sir F. Gowland Hopkins: The Task of Biochemistry (First Croonian Lecture).

NORTH EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, June 7th.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., *Dental Clinic*. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M. Surgical, Medical, and Children's Diseases Clinics. Operations.

HOSPITAL FOR SICK CHILDREN, Great Ormond street, W.C.

THURSDAY, June 9th.—4 P.M., Dr. Donald Paterson: Chronic Appendicitis in Childhood.

ROYAL NORTHERN HOSPITAL, Holloway road, N.

TUESDAY, June 7th.—3.15 P.M., Dr. Bruce Williamson: Demonstration of Selected Medical Cases.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, W.

THURSDAY, June 9th.—5 P.M., Prof. B. J. Collingwood: Molecular Movement in the Living Body.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester square, W.C.

TUESDAY, June 7th.—5 P.M., Dr. A. Whitfield: Eczema (2).

THURSDAY.—5 P.M., Dr. S. E. Dore: Mycosis Fungoides.

UNIVERSITY OF SHEFFIELD POST GRADUATE CLINICS.

FRIDAY, June 10th.—3.30 P.M. (*at the Royal Infirmary*), Dr. Barnes: Clinical Cases.

Appointments.

GRAHAM, D. C., M.B., Ch.B. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Selkirk District of the County of Selkirk.

MCKEOGH, J. W., M.B., Ch.B., D.P.H. Aberd., Medical Officer of Health and School Medical Officer for Bilston.

WILSON, ARTHUR J., M.B., Ch.B. Edin., Honorary Assistant Physician, Coventry, Warwickshire, Hospital.

The General Infirmary at Leeds: RICHARDSON, A., M.B., B.S. Lond., F.R.C.S. Eng., Hon. Surgeon, and CHAMBERLAIN, D., Ch.M. Leeds., F.R.C.S. Eng., Hon. Assistant Surgeon.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito Urinary Diseases, Vauxhall Bridge road, S.W.—Res. Sen. H.S. At rate of £200. Also Non-Res. Jun. H.S. At rate of £150.
Ashton under Lyne District Infirmary—H.S. At rate of £150.
Barking Town Urban D.C.—M.O.H., &c. £850.
Belfast, Mater Infirmorum Hospital—Hon. Radiologist.
Bristol General Hospital—Hon. Asst. S. to Ear, Nose and Throat Dept.
Bristol Royal Infirmary—Asst. in Pathological Research on Cancer. £100.
Burton on Trent Infirmary—H.S. £150.
Buxton, Derbyshire, Devonshire Hospital—Asst. H.P. £150.
Cardiff, Welsh National School of Medicine—Asst. in Medical Unit.
Charing Cross Hospital, Strand, W.C.—Registrar. £100. Also Hon. Anæsthetist.
Chester Royal Infirmary—Third H.S. £150.
Chiswick General Hospital, W.—Second Hon. Consulting Surg.
City of London Hospital for Dis. of Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Colchester, Severalls Mental Hospital—Asst. M.O. £510.
Durham County Hospital—Jun. H.S. At rate of £120.
East Sussex County Mental Hospital, Hellingly, Sussex—Jun. Asst. M.O. £350.
Elizabeth Garrett Anderson Hospital, Euston road, N.W.—Obstetrician.
Federated Malay States—Radiologist. $500–25–800 a month.
Glasgow Parish Council—Supt. of Poor Law Hospitals. £1500.
Hampstead General and North West London Hospital, Haverstock hill, N.W.—H.S. At rate of £100. Cas. Surg. O. at Out patient Dept. At rate of £100.
Herefordshire County Council and Bromyard Urban, &c., District Councils.—Asst. County M.O., &c. £685.
Herefordshire County Council and Dore and Weobley Rural District Council—Asst. County M.O., &c. £685.
Hospital for Women, Soho square, W.—Res. M.O. At rate of £100.
Liphook, Hants, King George's Sanatorium—Asst. M.O. At rate of £200.
London Hospital, E.—*Gynæcological and Obstetric Dept.*—Res. First Asst. £300.
Manchester City Education Committee—Two Asst. Sch. M.O.'s. £600.
Manchester, Hulme Dispensary—Res. M.O. £300.
Manchester Royal Infirmary—Asst. Surg. O. to Aural Out patient Department, two mornings weekly. £35.
Manchester, Royal Manchester Children's Hosp.—Sen. M.O. £300.
Manchester, Salford Royal Hospital—H.P., two H.S.'s, and Cas. H.S. Each at rate of £125.
Miller General Hospital for South East London, Greenwich road, S.E.—Cas. O. £150. H.S. £125. Also Hon. Asst. P.
North Middlesex Hospital, Edmonton, N.—Asst. M.O. £100.
Oldham Royal Infirmary—Three H.S.'s. Each at rate of £175.
Pinewood, Wokingham, Berks—Second Asst. M.O. £350.
Rochdale Infirmary and Dispensary—Jun. H.S. £200.
Royal Army Medical Corps.—Commissions.
Royal Chest Hospital, City road, E.C.—P. to Out patients.
Royal Free Hospital, Gray's Inn-road, W.C.—Res. Anæsthetist.
St. Giles Hospital, Brunswick square, S.E.—Asst. M.O. £7 7s. weekly.
St. John's Hospital, Lewisham, S.E.—Res. Cas. O. At rate of £100.

INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS

Fourth Annual Congress

The Congress, held at the Royal Horticultural Hall was opened at 10 30 A.M. on May 27th by Sir Arthur Stanley, the President. The morning session was given up to a discussion on Hospital Policy with particular reference to the Raising of Funds, introduced by Mr Walter Kewley, House Governor of the Middlesex Hospital In the afternoon Viscount Hambleden took the chair, when Prof Beresford Pite, F R I B A., read a paper on

Hospital Planning and Construction

It was, he said, probably the ideal of hospital officers that English hospitals should become standardised The governing *principle in England* was *the restoration of the patient's* health, and every part of the building, together with light, air, food, and drainage was designed to that end The most recently completed English hospitals showed how the essential factors had been harmonised to create a perfected type, capable of variation only in the equipment of the service rooms, baths, stores, &c., and in their connexion with the main arteries of administration

The practice of building sanitary annexes in isolated towers was being discarded on account of expense, and they were tending to become more accessible and more spacious The "cut-out" *system of* ventilation, which placed entire reliance on natural light and air, was unlikely *to* be improved upon. It was peculiarly suited to the windy, changeable English climate with its small temperature range

Foreign and English Practice

In America, where the temperature varied *from great* heat to great cold, and where the population were sensitive to draughts, open disconnecting lobbies and corridors were generally avoided For natural ventilation was substituted a complicated system of mechanical draught and exhaust ducts These, although they worked well, were difficult to clean and the machinery was expensive The *arrangement* would *not* appeal to the English architect, *nor suit the* English climate, conversely the English plan would be unsuited to the requirements of the States On the *Continent*, no standard had yet been reached, and experiments, with necessarily a certain amount of serious loss, were still being made. Europe was still divided between the corridor and pavilion types of plan In the very big modern German hospitals the detached pavilion was planned with the "large camp" idea Here architectural arrangement imposes, with its long corridors, a certain amount of tyranny over the administrative service

The best English hospitals, said Prof Pite, showed no trace of the influence of scholastic or classical architecture. Practical devotion to purpose was the manifest aim of the architect, and the seal of his success He had ample scope for his ideals of beauty in serving the dignity and essential aim of the building upon which he worked Our "standard" design was still insular Neither the Continental corridor plan, with its series of rooms arranged on either side of a dignified passage, nor the avowed picturesqueness of modern Scandinavian hospitals, nor the stately platoons of partitions in the Teutonic building, expressed to us the ultimate perfection.

The Outlook of the Patient A Suggestion.

The normal plan of a ward, by placing a window between each bed for cross-ventilation made every patient face the light and gave *him only* the foot of the opposite bed for scenery Prof Pite suggested that a line of framed screens about 6 feet high and 18 inches clear of the floor should be placed down the centre line of each ward The patient would then be relieved of the light opposite, and would live in surroundings more like those of a normal bedroom, especially *if the screens were tinted* in a quiet colour and decorated with an occasional picture, or fitted with shelves *for vases of flowers* This would make for privacy and variety alike, and would in no way hinder ventilation, supervision, or service. Mounted on rubber-tyred castors, the screens could easily be moved for floor-cleaning, or transported from room to room. To *give the* patient a little more variety of outlook than he had *at present*, the speaker suggested arranging beds up and down the wards instead of across them. Circular or *semi-circular* wards, though perhaps not very economical nor easy to adapt to a site, were considered by some authorities more cheerful for the patients and more convenient for clinical purposes.

Lifts.

The introduction of the lift was the most radical *of all* architectural developments, it had revolutionised the plans of civil and domestic architecture. Without it the high buildings of the New World would be *impossible. In* England, however, where more ground was still available, it had done *no more than facilitate the* working of the standardised plan, and had not fundamentally changed it, any more than had the speaking-tube Nevertheless, it might yet exert great influence As long ago as 1903, the late Sir John MacAlister had advocated vertical planning as the solution of many difficulties in the expansion of intra-mural hospitals The patrons would no longer have to seek wide extra-mural sites, and the wards would be raised above the gases of the town into purer air Sir John MacAlister had conceived the slogan of a "tower of healing" before the American upward movement had been recognised as more than an advertising scheme Vertical planning would reduce space and distance without sacrificing any of the achieved results of the standard The one thing necessary was a strengthened faith in the elevator, both in principle and in operation We ran expensive risks in other departments of hospital equipment, and our "conservative nervousness" was happily tending towards progress in this direction also Prof Pite concluded by summarising the spirit of modern hospital design as an alert conservatism founded on experience but with an extending reach towards progress

Discussion.

Mr A Griffiths (Secretary, East Suffolk and Ipswich Hospital) praised the Voluntary Hospitals Commission for laying down valuable lines for the guidance of bodies building small hospitals capable of adaptation to small purposes He said that it was no good adapting an existing building to serve as a hospital; such buildings were a burden to the communities they served Testators sometimes tied their bequests up to such buildings: they would do more good if they left a field and a sum of money and allowed the architect and hospital manager to build according to need Of the essentials of a hospital the wards were the least important They might be replaced in ten years, but the vital things were site, drainage, water-supply, the administrative block, central heating, &c Yet it was possible to raise money from the generous public for wards and *not for the other things* Here education was needed The psychological value of trees, flowers, and beautiful surroundings was very great, and should be considered in laying out a hospital Since the war, however, the fresh-air craze had largely abated Fresh air was a good thing, but a little warmth, comfort, and convenience in working were equally important Convalescent homes (again the speaker acknowledged the services of the Hospitals Commission) should be planned as hospitals

Colonel H Hunter (Bristol Homœopathic Hospital) recorded the success of the screen idea as put into practice at two Bristol hospitals His governing body had made the experiment of fitting a hot-air circulating apparatus This had been a great improvement, as the warmth could be regulated and the radiators and dust-collecting fireplaces eliminated It was, however, rather costly His authorities had appreciated the value of beautiful surroundings to the extent of spending £11,000 on laying out a garden

Mr A B Keay (Glasgow Ear, Eye and Nose Hospital) pleaded for better provision for the recreation of the nurses and general staffs, and gave instances of newer hospitals that had met the need for dancing, badminton, &c.

Mr F A. Lyon (Seamen's Hospital, Greenwich) told how a small plot of waste ground at the Albert Docks had been converted into hard tennis courts for the staffs of two Greenwich hospitals

Mr McGowan (*Chairman*, Whitehaven Hospital) asked for members' experiences with wireless installations

Mr W Richardson (London Hospital) asked whether the lecturer, in designing the semicircular hospital, took into consideration economy and convenience of administration, which it was difficult to combine with medical requirements

Mr J Gibson (Sunderland Royal Infirmary) spoke of the difficulty of *regulating the temperature* in temporary buildings, and of the delight of patients in being transferred from the æsthetic surroundings of a hospital to the domestic atmosphere of a convalescent home.

Mr E W. Johnston (King's College Hospital) pleaded, as an engineer, for space in the design to admit the laying down of ducts for electrical and steam power, so that these could be led to any point where they might be needed X rays had been brought to the bedside of the patient, in the future it was likely that other apparatus would be required in the wards, and it was important to make structural provision for that future Power channels in a hospital were as important as blood-vessels in the body

Mr William Pite, F R.I B.A, deprecated the introduction of the American tower hospital with its plenum ventilation.

Mr S R Lamb (Liverpool Voluntary Hospitals' Council) suggested that to deprive neighbours of fresh air by constructing high hospital buildings was to defeat the end of that building He asked whether the St Andrew's Cross the old Indian remedies, and it is easy to substantiate the contention of the advocates of the indigenous systems that methods of treatment which have been hailed as new discoveries of the modern school have had their counterparts in the East long ages ago Various developments of hydrotherapy and the deprivation of salt in dropsy may be quoted as instances of this in medicine, and light splinting and the early movement of fractures in surgery Modern scientific medicine should therefore not be regarded with hostility as a stranger in India, but welcomed as a younger branch of the same family The ancient wisdom has returned, reinforced by new ideas and discoveries which make it many times more valuable Accurate dissection has taken the place of scraping a decaying body with twigs, and founded the modern science of anatomy; careful experiments have placed the science of physiology on a sound basis, and enabled us to ascertain the functions of the principal organs, post-mortem examinations and other scientific methods of research have taught us a great deal about disease, and medicine and surgery, apart from advances within their own bounds, have profited enormously from all these basic sciences as well At the present day modern medicine and surgery are probably as highly appreciated in the East as in the West by those who are in a position to judge for themselves and to command the services of the best practitioners The difficulty has always been to make them available for the poorer people in rural areas

The Alternatives

There are, as above noted, three main ways in which medical aid may be provided in rural district—the perpetuation and extension of one or more of the indigenous systems, the creation of a special class, trained in elementary medicine on modern scientific lines (like the inferior veterinary assistants who used to be known as salutaris), or the employment of some permanent Government servants, such as the primary schoolmasters, also trained on modern lines, on a part-time basis

The first of these alternatives, the utilisation of the vaids and hakims, is at first sight attractive, and has been carefully considered It has, however, serious objections, some of which have already been referred to, and on further discussion it was found that these objections were realised fully by many advanced Indian thinkers A very distinguished Hindu social reformer, to whom the question was referred, was strongly opposed to the proposal, and only one member of a small conference of Indian gentlemen specially interested in such subjects spoke in favour of the proposition to revive the indigenous systems for rural work The difficulty of training at once arises If the vaids and hakims are to be used, are they to be trained in Eastern or Western methods or both? At the present day to restrict treatment to the methods of the indigenous systems in the light of all the advances of the nineteenth century would be unthinkable, and to call the practitioners Ayurvedic and let them work on a basis of modern science would not be fair or honest

The Proper Point of View

This question has hitherto, unfortunately, been considered and debated more on political, racial, and even religious lines than on its merits The experience of Japan in this connexion is very instructive As everyone knows, that country was at first violently opposed to all Western innovations, and medicine was no exception to the general rule It is even recorded that in the sixteenth century many Portuguese and native medical men practising the Western system—such as it was in those days—were put to death As late as the eighteenth century, indeed, the Japanese believed that the viscera of the European barbarians were transposed—i e, that instead of being in the position affected by all good Japanese, their livers were on the left side and their hearts on the right, and it was only in that century, when the first post-mortem examinations were made on European lines, that this erroneous impression was corrected From that time onwards, however, all seems to have gone well The existing system, a branch of ancient learning originally imported from China, and no doubt very respectable though hopelessly antiquated, was gradually displaced and modern scientific medicine adopted, until now Japan can boast 27 medical schools (18 of university standing) and Kitasato and Shiga are listened to with respect and admiration throughout the civilised world As regards the ancient Chinese system, it was recently stated by a distinguished Japanese official that it has almost expired, and that only in the most remote places are practitioners other than those of the modern school to be found in Japan

A Scheme in Being

Proposals were put up to Government in 1923 for an experimental trial of primary schoolmasters for elementary medical and surgical aid in villages Thirty of these men are at present at work in selected villages in the districts of Poona, Bijapur, Sholapur, and Dharwar The scheme is shortly as follows Selected primary schoolmasters are posted for a period of training of two and a half months to civil hospitals where special arrangements are made for them The men are taught elementary anatomy and physiology as in ambulance classes, and given practical first-aid instruction in medicine and surgery They work in the wards and out-patient department, and the course is made as practical as possible At the end of it they are expected to be able to dress wounds and ulcers, to treat sore eyes, and to recognise and treat with simple remedies some of the more important diseases They are also taught elementary hygiene (ventilation, safeguarding of water-supply, prevention of malaria, &c) Training is, of course, carried out in the appropriate vernaculars The cost of training works out at about Rs 72 for each man The equipment (village aid cabinet) costs Rs 250, and the upkeep of one aid-post comes to Rs 300 per annum inclusive The scheme is therefore very economical

It has proved successful, and the Upacharaks, as they are called, are now in great request wherever they are stationed In Bijapur, particularly, their work has met with cordial recognition from official and non-official observers, and the village officers and villagers in general are almost unanimously in favour of its extension Requests are frequently received from villages which have no Upacharaks for aid-posts to be established A general review of eight months' work, from June 1st, 1925, to Jan 31st, 1926, was taken in the Bijapur district, and the following remarks apply to the ten centres now in operation there. In these ten centres, during the eight months, 31,122 cases were treated These included malaria, dysentery and diarrhœa, eye diseases, skin diseases, wounds and ulcers, and many other affections Very favourable reports were received from the collector, the assistant collector, the president of the district local board, and the civil surgeon, amongst others Equally good accounts have come from Poona, the other district in which the Upacharaks were early established, and it is hoped that a combined report on the whole scheme will shortly be available

Investigation and Utilisation of Indian Drugs

Government has recognised the desirability of investigating such Indian drugs as have not hitherto been incorporated in the regular pharmacopœias, where reasonable grounds exist for believing that they are worth examination, and the pharmacological unit of the Haffkine Institute has for some time past been engaged in research work of this description It is also realised that some Ayurvedic and other indigenous remedies, the qualities and proper doses of which are well known, may usefully be incorporated in the village aid cabinets As time goes on no doubt these may be added to

Conclusions

1 The Ayurvedic and some other indigenous systems did very good work in their day, but they are based on erroneous theories, and cannot bear comparison with the modern system of medicine founded on recent advances in science The remedies are largely secret, and there has been no proper investigation of their active principles or standardisation of dosage

2 As regards the regular practitioners of modern scientific medicine and surgery, it is generally admitted that they are superior to any others Where they cannot be provided—chiefly for reasons of expense—it is desirable to establish some inferior class of practitioner, and for moderate sized villages these may be on a part-time footing It has been shown that primary schoolmasters can be very useful in this capacity at a moderate cost

3 To revert to any other ancient systems of medicine would be a very retrograde step They are not founded on scientific principles, and are entirely out-classed by modern scientific medicine It is admitted that any revival of the ancient systems must be largely dependent on the assimilation of scientific knowledge Ayurvedic medicine, on these lines, would be Ayurvedic only in name, and any such scheme would be an unworthy subterfuge

4 Apart from a revival of the Ayurvedic or other indigenous systems as such, every effort is being made to investigate Indian drugs, and these should be utilised whenever it appears desirable to do so

A MISUSE OF BUSINESS METHODS

WE have received from the holder of a municipal post as bacteriologist and pathologist a copy of a circular which had been sent to him from an institute of pathology connected with a metropolitan hospital The terms of the circular are not fortunate Addressing our correspondent as a general practitioner, while he does not happen to be in practice, the circular credits him with having already requested the institute for "an outfit for clinical material for examination" This request was never made The circular appears to have been based on what in trade circles is known as a "follow-up letter" More circumspection should be employed at the institute.

An Address

ON

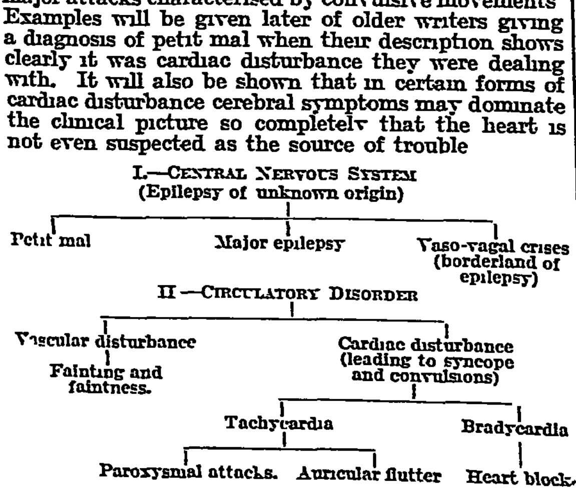
FITS AND FAINTS

Given before the Fellowship of Medicine

BY G A SUTHERLAND, C B E , M D EDIN ,
F R C P LOND ,
CONSULTING PHYSICIAN TO THE HAMPSTEAD GENERAL HOSPITAL , PHYSICIAN TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL

A DIFFICULTY often arises in the diagnosis of an attack of sudden loss of consciousness as to whether it was primarily cerebral, that is to say, of an epileptic nature, or primarily circulatory, that is to say, a faint or fainting attack This difficulty is much enhanced by the fact that in all probability the doctor never sees the patient in an attack and has only the statements of onlookers to guide him. In the case of adults and older children the patient may be able to give such details of the onset and the recovery as will make the diagnosis clear In the case of young children no such information is forthcoming, and all the doctor has to guide him is the mother's statement of what she saw or thought she saw A physical examination of the patient may throw no light on the subject, because in many cases there are no evidences of cerebral disease or of any diseases or disorders in the circulatory system in the intervals between attacks It is therefore of the greatest importance for a doctor to have as full a knowledge as possible of the various causes of fits and faints and of their accompanying features The subject is a large one and only certain points can be touched on here

Progress in our knowledge of heart disease and heart disorders has increased our means of diagnosing more accurately between fits and faints, both those which are seen and those which are unseen It has enabled us to state definitely that certain forms of sudden attack, with loss of consciousness, which were formerly classed as being epileptic in nature are really due to cardiac disturbance This will be fully illustrated later on A comparison of the fits and faints under discussion brings out this interesting fact, that while in the case of primary cerebral disturbance there are attacks of minor and major epilepsy, so in the case of primary cardiac disturbance there are minor attacks characterised by fainting, and major attacks characterised by convulsive movements Examples will be given later of older writers giving a diagnosis of petit mal when their description shows clearly it was cardiac disturbance they were dealing with. It will also be shown that in certain forms of cardiac disturbance cerebral symptoms may dominate the clinical picture so completely that the heart is not even suspected as the source of trouble



Assuming for the moment that there are two varieties of fits and faints, a mild form of fainting with loss of consciousness, and a more severe one with convulsive movements superadded, we shall find that there are two primary sources of disturbance These two sources are the central nervous system and the blood circulation, as shown in the accompanying chart

EPILEPSY OF UNKNOWN ORIGIN

The term "epilepsy of unknown origin" may provoke the criticism of those neurologists who can find a cause for every form of epilepsy, and will classify every type of convulsive seizure amongst "the epilepsies" Attacks of petit mal and of major epilepsy are still recognised by the bulk of the profession My purpose is not to add to our knowledge of epilepsy but to direct attention to some attacks which simulate epilepsy and may be erroneously diagnosed as such So far as my reading goes these difficulties do not seem to have presented themselves to neurologists—that is to say, there is little or no reference to them in their text-books The mystery of epilepsy will be solved when we have a clear understanding of the pathogenesis of an attack of petit mal. It is in connexion with attacks diagnosed as petit mal and occurring during childhood that mistakes are most likely to arise. If it be definitely accepted that petit mal is not accompanied by any general circulatory disturbance, and that attacks simulating it in other respects are always accompanied by definite and distinctive circulatory disturbance, we have evidence that these attacks have a different origin from those due to epilepsy

Sir William Gowers is very insistent on the fact that the colour of the face does not change during an attack of petit mal, although there may be slight pallor after it Later on the face commonly becomes flushed Both he and Sir Clifford Allbutt lay great stress on the fact that circulatory disturbance does not occur in epilepsy The latter writes .[1]

> "I have never had my finger on the pulse of an epileptic at the earliest moment of an attack, but scores of times, as for instance in the wards of lunatic asylums, I have felt the pulse at the instant of the seizure becoming manifest , I have never, however, found any characteristic change in the rate"

An attack of petit mal presents as a rule a clear-cut picture, but in some cases, in addition to the sudden momentary unconsciousness, there may be other characteristics Amongst these Gowers[2] mentions giddiness, falling down, jerks or starts of the limbs, trunk, or head, a sudden sense of fear, a sudden scream, and a sensation about the heart or the epigastrium In those cases in which a sudden stab or other sensation is felt in the precordium or epigastrium the common diagnosis of a "fainting turn" will appear to have received additional confirmation The other characteristics help to support a diagnosis of petit mal and to exclude that of a simple fainting attack.

FAINTNESS AND FAINTING

A fainting or syncopal attack is usually ascribed to cardiac weakness, but this is hardly correct A strong man may faint at the sight of blood or when being vaccinated Fainting is much more common amongst people with sound hearts than amongst patients with diseased ones Fainting is quite common in children between the ages of 8 and 15 years, but rare at those ages in the subjects of heart disease

The underlying conditions in those who are subject to ordinary fainting turns would appear to be an unstable and weak vasomotor system. The normal response to some nervous shock or unusual sensation does not occur in the vasomotor system, and blood accumulates in the abdomen and dependent parts The result is cerebral anæmia and loss of consciousness The condition is usually short-lived, without further complications, and recovery rapidly follows the recumbent posture. The patient may fall suddenly, but as a rule has sufficient warning of the oncoming seizure in the shape of a feeling of faintness to allow of his sitting down or holding on to some support The pulse may be small and weak during a faint, but the rate is not markedly affected The contractions of the heart are temporarily weakened, but this is probably due more to the small quantity of blood entering the heart than to loss of contractile power The important factor in all such fainting or syncopal attacks is the condition of cerebral anæmia, and construction did not depend for its efficacy on being surrounded by open country, and whether the money difficulties of service and supply that hindered the development of the excellent "bungalow" system could not be overcome It was a mistake to build wards too permanently

The **Chairman** spoke with appreciation of the collaboration of medical men on hospital boards The ultra-permanent American Hospital had its drawbacks, for it was too difficult to alter if necessary The difficulty of the semi-permanent type was that it required a very large site and was extravagant in time and labour Auxiliary services were outgrowing the hospitals in which their accommodation had originally been ample, he pleaded for the centralisation of sunlight, X ray, and electrical departments in new buildings He predicted a great future for lifts American devices must, however, save labour, and must carry a fair constant load to pay for their keep Most large London hospitals had wireless, and the rule here was, "Avoid loud-speakers like the plague" A pair of ear phones should be fitted at each bedside

Prof **Pite**, in his reply, said that ducts were necessary evils Hospitals must be planned with them, but their use should be avoided wherever possible Infection got pumped well into them and was then next to impossible to remove Machinery should not be made the permanent feature of the building, it was the most transitory factor of all Pipe-heating might have to be superseded by plate-heating, for instance, and then the expense was enormous The only permanent part of the building was the walls Nurses' recreation quarters, he thought, should be right away from the hospital The circular corridor was shorter, and saved labour

The Exhibition.

A Hospitals and Institutions Exhibition, opened on May 20th by H R H Princess **Arthur of Connaught**, proved of interest and use to those concerned with the equipment and construction of the modern hospital, every department was represented in the collection of exhibits and a good idea could be formed of the standard reached in labour-saving appliances and new materials

The operating theatre equipped by Messrs Allen and Hanbury had a fine operating table with "Monel" metal top "Monel" metal is much used in American hospitals and is excellent for kitchen work as well as for sterilising drums and the like, it wears well, though it becomes duller with use and should have a future in this country unless the cost is too high The instruments shown were all of rustless steel, door-handles, fittings and taps of this metal retain their smart appearance without the labour of constant polishing The illumination of the table was of the "Holophane Circuit Type" in which several lights are concentrated on the field of operation, a type which is also common in America, though not possessing the flexibility of such fittings as the "Scialytic" The rubber floor was pleasant to walk on, but the perfect jointless flooring is still to be found The "Decolite" floor shown by Bell's United Asbestos Company has advantages of its own, and the imitation marble, "Calbonite," of the same firm, may prove useful for dadoes

The kitchen equipment department was fully represented, one of the most interesting exhibits being Benham and Sons' insulated food trolley, constructed on the principle of a thermos flask with containers for hot and cold food, the top in "Monel" metal and the sides in aluminium (a material which, unfortunately, has defects as well as merits) The dish-washing machines much used in America are evidently finding their way into this country, and two good types were shown—the "Victor" dish-washing machine and the "Crescent" where dishes are packed in trays and subjected to rinsing and disinfecting by jets of boiling water Many other labour-saving machines were shown, such as the "Hobart" mixer (whose merits are well known) and the electric potato peeler by Mabbott and Co

The question of heating, especially of private wards, is much debated at the present time and the merits of gas and electricity were both well set out, the former by the Gas Light and Coke Company, who showed illustrations of the work carried out at Westminster Hospital, and the latter by the "Electro-Vapour" radiators, which have been proved convenient in operating theatres, as for instance at the Hereford General Hospital The "flush hospital" door which is more than ever used in up-to-date hospitals, was represented by a type made by Ripper, Ltd, of Castle Hedingham, where a sound-resisting material, "Celotex," is used inside the framing

A collection of hospital plans would have been in place at the exhibition, but the plans of the Seamen's Hospital at Tilbury, by Messrs Collcutt and Hamp, though a very good and well-designed example, were the only exhibit of this kind The omission of the sanitary tower in the ward plan shows the post-war tendency to dispense with the cross-ventilated lobby which used to be considered an essential.

THE MEDICAL WOMEN'S FEDERATION.

The half-yearly meeting of the council was held at Manchester from May 12th to 14th, the President, Dr Christine Murrell, in the chair

A pamphlet prepared by the Venereal Diseases Standing Committee, dealing with the duty of the State in the control of venereal diseases, was referred to the local associations for consideration Appreciation was expressed of the work of the League of Nations in their report on the traffic in women and children, and a resolution was passed welcoming the appearance of the report and expressing the hope that the Committee of the League would continue its investigations from the health point of view, since the Federation was convinced that such investigation would demonstrate the medical futility of the whole regulation system A further resolution was passed recording the unshaken belief of the Council that the non-compulsory system of attempting to eliminate venereal disease in force in Great Britain and Holland has produced, and promises to produce, the best results, and protesting against any attempt to graft on to it any form of compulsion or to reintroduce the hurtful association of venereal disease with the police.

The Standing Committee for the Defence of Married Medical Women reported that a meeting had been held to consider what steps might be taken to support the proposed Married Women's (Employment) Bill The proposal to get up a petition to Parliament had been abandoned in view of the shortness of time, but many individual letters to Members of Parliament had been written

The Menopause Subcommittee reported that two questionnaires designed to carry out an investigation on a wide scale into the phenomena of the menopause had been widely circulated

The question of underpaid posts was dealt with in the report of the Standing Committee on Public Health To aid in dissuading women from accepting black-listed posts, a pamphlet was passed by the Council for distribution to newly-qualified medical women and D P H students, and to deans and secretaries of medical schools Cases of underpaid posts applied for or accepted by medical women during the last six months were reported Where their names could be obtained, candidates had been approached several of them showed great public spirit and retired The Council noted that no member of the Federation was among those who accepted these posts

A new Standing Committee on Psychological Medicine was formed, and reports were received of the work of various funds administered by the Federation.

THE AMATEUR GOLF CHAMPION

For the second time in the history of the amateur golf championship the honour has been won by a medical man Dr William Tweddell, who is a native of Durham, spent his early years in Yorkshire where he first learnt to play golf, showing considerable promise while still a boy During his years of service in the war he had little opportunity for practice, but when in 1919 he entered the University of Aberdeen as a medical student his golfing prowess soon became evident He was a member of Murcar Golf Club, Aberdeen, and played in the University team Dr Tweddell qualified in 1924 and after holding resident posts at the Royal Infirmary, Aberdeen, and in Manchester, he settled in practice at Stourbridge His success is no surprise to those who have watched his progress and will give great satisfaction to all members of his old university. We offer him cordial congratulations

BLOOD TRANSFUSION FOR BRONCHIAL ASTHMA

Since anaphylaxis, malnutrition, and anæmia may all be factors in the ætiology of asthma, transfusion of whole blood might reasonably be expected to have therapeutic value The anæmia would, of course, be relieved directly or by stimulation of the blood-forming organs, and it is possible that sensitisation to proteins might be changed Dr W T McBroom has recently recorded[1] a series of five cases treated by direct syringe transfusion He found that the asthmatic attacks ceased immediately in four of the cases, whilst in the fifth they were reduced in frequency and intensity In addition to the direct relief the general health improved and the weight increased The three younger patients had failed to respond to all other methods of treatment, the older ones had had asthma of long standing, and the resulting emphysema and embarrassment of the right heart could not be removed by transfusion It must be remembered, however, that patients with asthma are apt to improve for a time on any régime or after any operation that impresses them sufficiently and Dr McBroom's five cases are insufficient support for the conclusion that transfusion is a useful specific treatment for bronchial asthma —a conclusion which would conflict with the experimental results of other workers led me to the conclusion that there was no petit mal, and that the attacks were all of the same character and due to the cardiac disturbance In the case of the girl all of the attacks were of the same nature, and in all of them which were observed the heart-rate was abnormally rapid The sudden onset and the sudden cessation of this tachycardia coincided with the period of an attack Exertion seemed to induce an attack at times and it seemed to bring on some symptoms of an attack, which led the child to take less and less exercise With cessation of exercise, from progressive heart failure, the attacks ceased entirely In the case of the boy he has been under treatment for seven years for petit mal, and in all probability his attacks were really cardiac in origin, and not epileptic in character From the onset the attacks have followed usually on exertion, and as the years passed they came to be definitely associated with exertion or nervous shock The boy came to learn this fact for himself and would not over-exert himself because he knew it would make him faint This is very unlike a condition of petit mal The first suggestion of any heart trouble was at the age of 11 years Writing in 1926, his mother says —

---

[1] Canadian Medical Association Journal, April 4th.

> "In August, 1925, he was much worse than he is now, by that I mean he then had to walk very slowly, and if he went upstairs his heart would beat at an alarming rate, or even to laugh much would make him feel bad "

At the present time one can bring on an attack of tachycardia by making the boy run, but he is very conscious of the cardiac discomfort thus induced and will not push his exertions beyond a certain point Comparing his present attacks with those described at the age of 4 years and onwards, one cannot find that there is any essential difference

Turning from my own experience of this type of case to that of others I find the following in an article on cardiovascular disease in Garrod's "Diseases of Children"[4] The section is on disturbances of cardiac rhythm and the paragraph is headed Tachycardia and Epilepsy —

> "There are some cases in which paroxysms of extreme rapidity of the heart's action occur in children who have previously suffered from epilepsy Two such cases have come under the writer's notice The first, a boy of 9 years, had been subject to epileptic fits up to the age of 4 years, and from infancy had attacks of what the mother termed palpitation of the heart Although the epileptic fits had ceased, about every three weeks violent attacks of palpitation occurred without apparent cause and always at night Between the attacks the rate was about 80 per minute and the action slightly irregular The second, aged 1 year and 5 months, four days after a fit, had some palpitation of the heart lasting several days, and since then had been subject to attacks about once a week These always commenced in the morning and lasted for some hours The heart was apparently sound Both these cases improved slowly under treatment with bromides "

In the light of my own cases I venture to suggest that there was no epilepsy here but merely the results of paroxysmal tachycardia

Hirschfelder,[5] in a chapter on paroxysmal tachycardia, lays stress on the fall of arterial pressure which induces cerebral anæmia, and is accompanied by weakness, vertigo, and even syncope In one patient the syncopal attacks had led some physicians to diagnose heart-block with the Stokes-Adams's syndrome, but further observation showed that the cerebral anæmia resulted not from bradycardia, but from paroxysmal tachycardia Esmein and Dougelot,[6] in an article on the syncopal form of paroxysmal tachycardia, describe this as being usually less severe than that of the Stokes-Adams's type Dr Arlie Barnes[7] found that—

> "cerebral manifestations, consisting of hemianopsia, temporary blindness, fainting, falling with or without loss of consciousness, and epileptiform seizures occurred in 15 of 104 cases of paroxysmal tachycardia that were studied "

These experiences of the symptoms associated with paroxysmal tachycardia must be kept in mind if one is not to be placed in the position thus described by the late Dr George Balfour[8] —

> "Nothing can make a man feel more helpless than to be brought for the first time face to face with a bad attack of tachycardia, of the nature of which he knows nothing, and, perhaps, may never even have heard of its existence."

AURICULAR FLUTTER

A study of auricular flutter throws further light on the occurrence of syncopal attacks associated with tachycardia An attack of auricular flutter can be distinguished in many cases from one of paroxysmal tachycardia only by means of an electrocardiographic record It is characterised by a very rapid ventricular rate, reaching sometimes from 200 to 220 beats per minute or even, according to some, 300. As a result the ventricular contractions at the onset may be so weak that the patient loses consciousness An attack of auricular flutter may be sudden, brief, without any previous symptoms of ill-health, and without any subsequent change in the heart If the attack is brief, and the patient has a syncopal attack it is very probable that a diagnosis of petit mal will be made Attacks of auricular flutter occur but rarely in infancy and childhood, they may develop in early adult life, but they are much more common in later life—the period of degenerative heart disease Syncopal attacks are quite common and are clearly due to cerebral anæmia, the weakened contractions of the left ventricle failing to maintain a sufficient supply of blood to the brain Sir James Mackenzie[9] records a number of cases in which the patient suddenly lost consciousness and fell down He says that some have attacks of unconsciousness lasting from a few seconds to hours, and that falling to the ground is not uncommon. In his monograph on "Auricular Flutter," Dr W. T. Ritchie[10] says that the initial symptom of each paroxysm is palpitation, which is often very distressing In some instances vertigo ensues as a result of the weak and extremely rapid ventricular action, and there may be occasional syncopal attacks He has noted that a paroxysmal attack of flutter may be excited suddenly and without any warning, under the influence of emotion or physical exertion It would appear from these observations that the cerebral symptoms of an attack of auricular flutter may be identical with those described in connexion with paroxysmal tachycardia

BRADYCARDIA AND HEART-BLOCK.

The type of bradycardia which is associated with heart-block is due to an interruption of the normal progress of the heart beat through the genetic system. Under certain conditions of heart-block the patient is liable to fainting attacks with loss of consciousness, and sometimes falls suddenly. In many cases of heart-block there may be a slow but regular action of the ventricle, in which no symptoms of the nature we are dealing with will arise In other cases there is a prolonged ventricular pause leading to cerebral anæmia and loss of consciousness The attack may be brief and sudden and the patient, if talking at the time, may simply cease and then resume where he left off This form of attack is very easily mistaken for petit mal In other cases there is loss of consciousness and the patient falls to the ground In more severe cases there is some twitching of the muscles of the face, and this epileptoid seizure may develop into a general convulsion—the well-known Stokes-Adams's syndrome These various results present in cerebral anæmia have been accurately measured by Sir James Mackenzie[11] in terms of the length of the ventricular standstill

> "When the ventricle stands still over 10 seconds cerebral symptoms dominate the picture First there is giddiness, then loss of consciousness, and if the standstill exceeds 15 seconds, twitching of muscles as those of the face, the neck, and arm follow If the standstill of the ventricle extends over 20 seconds violent convulsions and stertorous breathing are set up As soon as the ventricle begins to beat all these phenomena disappear, the patient quickly recovering consciousness."

when this has reached a certain stage loss of consciousness follows

The term cerebral anæmia is a convenient one but it lacks precision In all probability a syncopal attack is not due so much to the small amount of blood which reaches the brain as to the sudden fall in blood pressure which takes place in the cerebral arteries. As Gowers [3] has pointed out, consciousness is a function of the brain cells, and loss of consciousness, as in an ordinary fainting attack, cannot be due to a temporary absence of blood cells, for it is lymph and not blood which comes in contact with nerve cells. At the onset of unconsciousness the supply of lymph is sufficient for the metabolic processes required by functioning nerve cells He emphasises the different causes at work in the loss of consciousness in epilepsy and in fainting "We have to conceive the loss of consciousness as occurring spontaneously in epilepsy, and as due to a sudden diminution in the intracranial pressure in syncope acting as a mechanical influence" When I use the term cerebral anæmia in connexion with attacks of syncope due to circulatory disturbance, the above remarks on the accompanying fall in blood pressure should be kept in mind

Although there is such a thing as a fainting habit, possibly less common now than formerly, a faint is usually an isolated occurrence If a mother states that a child has "fainted" five times in a day or a week we naturally think rather of petit mal It is common to find a definite cause for a fainting turn, such as a hot stuffy atmosphere, an attitude requiring prolonged strain, a sudden fright or other nervous shock, or severe pain No such definite preceding cause is usually present in connexion with attacks of petit mal There is a certain fainting type of person, with the poor vasomotor tone already referred to, who is subject to chilblains in winter and blue cold hands in summer, who turns pale or flushes upon slight provocation, who often shows postural albuminuria, and whose staying power on exertion is slight The accompanying conditions of these fainting turns are such that a correct diagnosis can usually be made if all the circumstances are carefully inquired into, and if the sufferer is old enough to describe his sensations intelligently

CARDIAC DISTURBANCE IN THE GENETIC SYSTEM.

For clinical purposes it is useful to divide the heart into two parts, the contracting muscle and the genetic system The driving power of the heart lies in the contracting muscle, but the control of this function lies in the genetic system, which determines the rate and rhythm and regularity of the heart beat The genetic system is the name given by Sir James Mackenzie to that specialised tissue in the heart which commences at the sino-auricular node and extends through the auricles, the auriculo-ventricular node, and the auriculo-ventricular bundle to the ultimate branches of this bundle in the muscle-fibres of the ventricles He prefers the term genetic system to conducting tissues, as in this system is the starting-point of the heart beat and it does more than conduct impulses, its activity means an impulse transmitted from cell to cell, each cell discharging its energy in the process The fits and faints we are now going to consider are due to disturbance of the normal working of the genetic system

These disturbances in the genetic system are of two kinds. first, a condition of tachycardia or abnormally rapid action of the heart; and, secondly, bradycardia or abnormally slow action of the heart In each of these conditions there occur faints which may be diagnosed as petit mal, and convulsive seizures which may be diagnosed as major epilepsy In each of these conditions the syncopal attacks are due to the usual cause—namely, cerebral anæmia of a temporary character The heart fails to supply a sufficient amount and pressure of blood to the brain If this cerebral anæmia is sufficiently prolonged a convulsive seizure ensues

PAROXYSMAL TACHYCARDIA

This is a clinical term signifying a sudden increase in the rate of the heart from normal to 160-200 beats per minute, lasting for some seconds, or minutes (or hours), and followed by a sudden cessation of the tachycardia, with or without some irregular action at the close The patient is usually conscious of the new cardiac rhythm, feels a fluttering sensation on the chest, is conscious of the heart racing, and may have a feeling of exhaustion and prostration during an attack and afterwards Many such attacks occur in patients who present no other signs or symptoms of heart disease, who suffer little inconvenience during an attack, and who in my experience have grown up to perfectly healthy adult life. But there are other cases in which the onset of the tachycardia is attended by syncope and falling down, and other characteristics which may lead to a diagnosis of petit mal Examination of the patient during an attack reveals the condition of pathological tachycardia—that is to say, a heart-rate above 160 per minute It will be found that when the attack ceases and the symptoms pass off the heart-rate has returned to normal After watching a series of these attacks one is forced to the conclusion that the tachycardia is the cause of the seizure, and that in all probability the small amount of blood discharged by the heart has produced the syncopal attack If the patient is not seen in an attack the doctor may easily be puzzled and an erroneous diagnosis may easily be made Here are two cases in which I blundered as the result of my ignorance of this condition.

CASE 1 —A female child at the age of 2½ years began to suffer from screaming fits at night In an attack she was said to become stiff and turn grey in colour She was admitted to hospital at the age of 3½ years with a provisional diagnosis of petit mal There was no evidence of any organic disease and the child was healthy in appearance Attacks occurred in the hospital at irregular intervals, sometimes by day, sometimes at night Here is a description of a typical attack The child was sitting in a chair when she commenced crying, rested her head on the side of the chair, and then suddenly collapsed on the floor She was unconscious, the face was pale, the lips rather blue, and the pulse-rate was 180 per minute She recovered consciousness within a minute of falling but was rather dazed at first Two minutes later the pulse-rate was found to be 70, and then it gradually rose to between 80 and 90 In some of the attacks her limbs became rigid and her teeth were clenched In all of the attacks a condition of tachycardia was present, of a purely temporary character, but the rate, the sudden onset, and the sudden offset showed that a new rhythm was present in the heart during the attacks

CASE 2 —A boy of 4 years began to suffer from "fainting fits" and had five attacks in the course of the following 12 months An attack began with the boy's screaming loudly and falling down After a few minutes he went off to sleep and then woke up quite cheerful He had nose bleeding as the result of one fall and a bump on his forehead as the result of another The boy appeared to be perfectly healthy in every way and his doctor and I considered that the attacks were due to petit mal, and treated him accordingly For the next seven years he took much bromide but the attacks continued at intervals, the longest interval being two years He was never seen by us in an attack, and no question as to the diagnosis was raised until he was 11 years old He had had five attacks in the first six months of the year, which were described as "fainting" attacks without screaming They followed on some sudden shock or during active exercise He had been playing games at school but in a quiet way, with some one to run for him at cricket It was then found that any active exercise, like walking upstairs quickly, would bring on an attack of tachycardia, the heart-rate being 180 per minute The boy complained of the beating of the heart, felt generally uncomfortable, and looked dazed and anxious In about two minutes the tachycardia ceased abruptly, and after some irregular beats the normal rate of 60 was resumed He was old enough to describe his own sensations in connexion with the fainting attacks "When I faint my heart thumps and gallops and then it seems to try and stop, and then I seem to lose my bearings"

It may be suggested that in these two cases there was a double condition of petit mal and attacks of cardiac syncope Observation of the patients has

Some Aspects
OF
INFLAMMATION AND INFECTION *

A Course of Four Lectures delivered for the University of London at Guy's Hospital on May 20th, 27th, 31st, and June 3rd, 1927,

BY E H KETTLE, M D, B S, M R C P LOND,
PROFESSOR OF PATHOLOGY AND BACTERIOLOGY IN THE UNIVERSITY OF WALES

LECTURES III AND IV *

IN the previous lectures we have discussed the different types of lesions which result from the damage of the tissues by various agents We have now to consider whether these observations are of merely academic interest or whether they have any practical bearing in helping us so to understand the inflammatory process that by the intelligent utilisation of our knowledge we can control it This is really what we have in view because, for practical purposes, inflammation and infection are, in the microbic diseases, synonymous terms The medical officer of health is perfectly justified in calling milk infected if it contains virulent bacteria; no one but a hyperpurist would object to his use of the word Again, a bacteriologist may properly describe a patient in whose throat virulent diphtheria bacilli are growing as infected, though he may exhibit no signs of illness But for the pathologist infection implies something more It implies the establishment and growth within the tissues of a micro-organism The mere presence of an organism is not sufficient to warrant the use of the word, there must also be definite changes in the tissues In other words, pathologically speaking, infection cannot exist without inflammation

The following experiment, which was suggested to me by Dr W E Gye, will make this point clear (Fig 1)

Twelve mice were inoculated into the right flank with washed and heated spores of *Vibrion septique* Six other mice were inoculated into the right flank with the same suspension of spores but with the addition of 5 mg of calcium chloride The following day these six mice were dead with typical gas gangrene, but the first 12 remained perfectly healthy Two days after inoculation one of them developed gas gangrene, but the other 11 were unaffected Four days after the original inoculation six of these 11 mice were inoculated into the right flank with 10 mg of calcium chloride, they died of gas gangrene within 36 hours, but the remaining five are still alive and healthy. In other words, the mere presence of the organisms was not sufficient to determine pathological infection, they remained latent in the tissues until defence-rupture was brought about

THE SPECIFICITY OF INFLAMMATORY LESIONS

It becomes of the first importance, therefore, to decide whether the different inflammatory processes which have been considered are really specific and invariable or, at any rate, sufficiently so to give a working basis to an attempt to combat infection Does the typhoid bacillus, for example, always produce the same reaction in the human body, and is this reaction so characteristic that we can with certainty distinguish it from the reactions brought about by other pathogenic microbes? In many modern textbooks the specificity of infections is definitely taught, and in the older literature we find much attention devoted to the various tissue changes which follow infection with different organisms But in practice the tendency nowadays seems to be to disregard this point of view altogether, and to wage a standardised, and quite illogical, warfare against all types of microbes Indeed, Powell White has recently expressed the view that the inflammatory process is not specific, but that any variations in reactions are due to the intensity of the irritant Even with our present imperfect knowledge this attitude is untenable, and we may reasonably hope that a closer analysis of infections will reveal further distinctions which have so far escaped us

It must always be remembered that the clear-cut observations of the chemist and physicist are scarcely within the reach of the biologist Individual animals vary enormously in their behaviour under experimental conditions, and local differences in the structure of the tissues in animals of different species make for further complications The mouse, for example, with its loose attachment of the skin to the body wall, permits of a localisation and concentration of an inoculum which can scarcely be obtained in the rabbit And in the dense collaginous cutaneous and subcutaneous tissues of the rabbit the reaction to an irritant is very different from that occurring in the delicate tissues of the mouse

If, bearing these limitations in mind, we examine certain of the inflammatory processes, we find that in those due to chemical or physical agents a high degree of specificity obtains Calcium and silica inoculated into the subcutaneous tissues of the mouse bring about a sequence of changes which are definite and regular, the reactions vary in intensity according to the doses administered, but in essential features they are always the same Turpentine, again, produces in the subcutaneous tissues of the rabbit a lesion which can scarcely be mistaken for anything else Similarly, more inert substances such as carbon, aluminium oxide, cholesterin, and simple foreign bodies, also give rise to characteristic lesions I mention only those reactions with which I am especially familiar, but I see no reason to doubt the possibility of recognising a whole range of specific non-bacterial inflammations No doubt many substances may call forth practically identical changes—there may, in fact, be a series of "group reactions"—but we may reasonably claim that in the normal animal a constant irritant will produce a constant inflammatory reaction

Turning now to the second group of inflammations, those due to bacteria, we find they are much less constant Whereas in the chemical and physical reactions the exciting agent can be measured and controlled, and the tissues react as regularly as any living substance can be expected to do, in this group the exciting agent and the host are subject to such biological variations that only by the study of a vast mass of material is it possible to reduce any particular infection to its fundamental characteristics An organism of normal virulence will produce

---

* Lectures I and II appeared in THE LANCET last week. All the lesions described were illustrated by lantern slides

He recognises the possibility of mistaking the nature of these attacks when the doctor has only the patient's own experience to guide him

> "When a patient states that he loses consciousness for a brief moment—a few seconds—and immediately recovers, sometimes falling down, it may be surmised that his attack is due either to a temporary heart-block or petit mal If the patient is young the latter may be suspected, if in later life—over 40—the former"

It is interesting to read the experiences of former clinicians who recognised the phenomena present in heart-block, although they were ignorant of the nature of this condition Stokes and Adams recognised the epileptoid attacks associated with a slow pulse Hilton Fagge[12] (1888), in the chapter on minor epilepsy or petit mal, gave the following account of an attack which was evidently due to heart-block —

> "Some years ago while I was one day listening with the stethoscope to the heart of a man whom I have never seen before, its beats suddenly ceased I looked up and saw that his face had turned deadly pale He said that he was going to faint and reclined back on the chair from which he had risen I could feel no pulse at his wrist and for an instant I thought he might be going to die, but I had hardly time to ring my bell when the colour returned to his face and I found that his heart was beating again Presently there was a little twitching of the muscles in one or both hands In a minute or two he was able to tell me that he often had 'fainting fits' and that some years back he had been subject to epileptic seizures It appeared clear that the attack which I had witnessed was one of minor epilepsy"

It appears equally clear now that this was an attack of heart-block, and in all probability the previous "epileptic seizures" were of the same nature

Sir William Broadbent[13] (1897) wrote as follows on the symptoms of fatty degeneration of the heart —

> "The epileptiform attacks are not often violent but resemble petit mal rather than a typical epileptic fit, while, however, the convulsion may not be so severe there is profound unconsciousness—not like epileptic coma, but of a syncopal character—and the pulse may be extremely infrequent, sometimes less than 20 in the minute In my judgment the heart failure manifested by the slow pulse and the consequent arrest of the cerebral circulation are the cause of the fits, and it is not the epileptiform attack that affects the action of the heart By the time any of these forms of attack occur the diagnosis of fatty heart is usually sufficiently clear, but I have had under observation a case of very slow pulse with petit mal in which the strength and volume of the pulse and the degree of impulse of which the heart was capable precluded the idea of advanced degeneration"

The clinical observations of this physician—who was a great cardiologist and no mean neurologist—show clearly that he was dealing with attacks of heart-block with standstill of the ventricles and not with a condition of "fatty heart" or of petit mal

Although, as Mackenzie states, heart-block with syncopal or convulsive attacks is much more common after the age of 40, the possibility of its occurrence in early life must be kept in mind A good number of cases of congenital heart-block are now on record due to some defect in the interventricular septum Those patients are liable at times to attacks of giddiness and fainting In acute infective fevers, such as diphtheria, heart-block may develop, but any symptoms in these cases are not likely to be mistaken for those of petit mal as the patient is under close observation It is not so well known that heart-block accompanied by faints and fits may be an early sign of rheumatic infection I have recorded elsewhere[14] the following case —

> A schoolboy of 17 years was noticed by a brother at 3 A M. to have a fit The patient had just returned to bed after having risen to take a drink of water From 3 A M to 5 A M. he had a series of fainting turns, and at 5 A M another fit The doctor who attended the case found that numerous fainting turns occurred in which the patient turned pale but did not lose consciousness, he complained of feeling faint In the more severe attacks or "fits" he became pale, the legs and arms were fixed, and he lost consciousness, some twitching of the limbs and face occurred, he breathed deeply, the face became flushed, and he recovered consciousness The severe attacks occurred only occasionally until midday and then became more frequent After a severe attack there was usually vomiting or violent retching
>
> When I saw him at 2 P M the same day the boy was feeling tired and exhausted The pulse was at times steady and regular at 80 per minute, and at other times irregular with pauses of varying length These pauses were characterised by a feeling of faintness on the part of the patient During 20 minutes the pulse on two occasions was quite imperceptible and the ventricles ceased to beat for long intervals and each time a "fit" as described above occurred The periods of ventricular standstill were so prolonged that one wondered if the ventricle would ever resume beating

By observation of the heart and pulse during the faints and fits one was able to recognise that the condition was circulatory in origin and not epileptic Taking the attacks by themselves one could easily have adopted a diagnosis of epilepsy The underlying condition was apparently a toxic disturbance of the genetic system, due to acute rheumatic infection, and leading to heart-block of an intermittent character, and, as it proved, of a temporary nature.

Some Further Problems.

While in the case of bradycardia due to heart-block the attacks of syncope and convulsive movements can be understood easily as the result of cerebral anæmia from cessation of ventricular action, the exact conditions in connexion with paroxysmal tachycardia and auricular flutter are not so clear There is here no cessation of the circulation The heart continues to beat and, as a rule, regularly. The syncopal attack usually occurs at the onset of the new rhythm Many patients have similar attacks of tachycardia and yet never show any signs of fainting What special factor is it which determines a fainting attack in one patient and not in another, or in one attack and not in another? It may be suggested that there is more disturbance of the blood flow through the cavities of the heart at the onset of the new rhythm, and that this leads to a diminished supply of blood to the cerebrum Later the heart accommodates itself to the changed condition and more blood reaches the brain In many of these cases of tachycardia the auricles and ventricles are contracting at the same time—as graphic records show—and the refilling of the cardiac chambers during diastole must be a very partial process It may be that want of blood in the heart is the direct cause of want of blood in the brain In the case of auricular flutter Sir James Mackenzie considered that the weakness or absence of the pulse was due to the ventricle responding for a brief period to each auricular contraction It is clear that a heart beating at the rate of 200 to 250 per minute has very little driving power, as well as very little blood to expel A fainting attack under such conditions is easily understood, but experience has shown that similar attacks may occur when the heart-rate is not more than 180 per minute These problems require further study, and possibly closer observation of the circulatory conditions present at the onset of an attack may help their elucidation

But apart from theoretical considerations we must all be aware of direct observations which are incompatible with the view that immunity is concerned entirely with the circulating blood A patient severely ill with typhoid fever may have a high agglutinin content of his blood serum, while on the other hand, it is said that individuals who have acquired active immunity against such diseases as enteric fever, plague and cholera remain relatively resistant long after demonstrable antibodies have disappeared from the blood H D. Wright has recently published some extremely interesting observations bearing on this He shows that in immunised rabbits pneumococci rapidly and permanently disappear from the blood stream, but that the serum shows no constant increase of the usual antibodies. And many cases of subacute infective endocarditis exhibit a phenomenon which is not sufficiently appreciated (Figs 2 3 and 4) In these cases colossal numbers of organisms grow on the endocardium, actually in the blood stream, but should they become detached and carried to other parts of the body they seem unable to proliferate. This is especially well seen in the kidneys when emboli of microbes are caught up in the glomeruli for progressive lesions scarcely ever develop; the organisms which proliferate freely when bathed by the blood stream are killed off by the tissue cells and healing takes place with the minimal amount of scarring

I do not think, therefore, that we shall achieve our end if we limit our study to the blood But at the same time I do not suggest for one moment that antibodies are of no importance. The serological changes of immunity are obviously part of the profound alteration in the body as a whole which follows infection: there can be no two opinions about that; the only question that arises is how big a part do they play? For me at least, this question is still unanswered and is likely to remain unanswered until it is more generally recognised that the chemist and physicist have in immunology a fruitful field for their labours

Section of a human kidney from the same case of subacute infective endocarditis shown in Fig 2 The section shows completely fibrosed glomeruli (A) and one partly fibrosed (B) There is some interstitial scarring

TISSUE REACTIONS AS A FACTOR IN IMMUNITY.

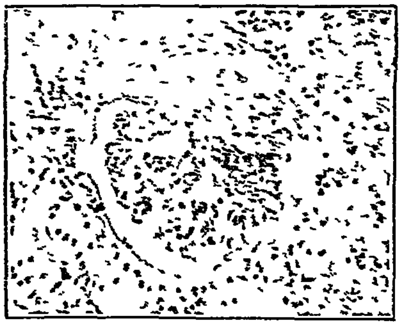
If on the other hand we devote ourselves to the study of tissue reactions what guarantee is there that we shall meet with success? There is very little I am afraid, to encourage us, for comparatively little work has been done in this direction. The work of Metchnikoff and his school has established the importance of the phagocyte, but this is scarcely the same thing Koch some 40 years ago, demonstrated that the tissues of the tuberculous guinea-pig react in a remarkable way to a second infection with tubercle bacilli, and more recently continental pathologists have devoted much attention to the analysis of primary and secondary tuberculosis in man. From this work it appears to be established that the almost universal primary tuberculosis of infancy or childhood is successfully overcome in the majority of people and that the characteristic lesions heal with a specific tissue reaction But this infection permanently modifies the tissues of the host and should a second infection occur in later life it is definitely different from the primary one both in the distribution and progress of the lesions and in their histology.

But experimental work in this direction has been relatively neglected, and I propose, therefore, to devote the rest of the time at my disposal to discussing the possibilities of this method of research

THE MECHANISM OF DEFENCE-RUPTURE.

As I have already said, we may enlarge the scope of our investigations by using animals which have been artificially rendered more immune, or more susceptible, to any particular organism. The latter method is the simpler, and it is the one with which I have chiefly worked We owe our knowledge of its possibilities to the investigations into the pathology of gas gangrene carried out by Bullock and Cramer in 1918 These authors found as others have done before them, that surface cultures or washed broth cultures, of *B welchii* are practically non-pathogenic to mice and guinea-pigs, though small quantities of whole broth culture produce a fatal gas gangrene in 24 hours They came to the conclusion that these animals are naturally immune to *B welchii*, and that if gas gangrene is to be produced there must be present, in addition to the host and the organism, a third or accessory factor. Clinical experience confirmed this impression, for while many wounds on the western front were infected with *B. welchii*, or harboured these bacilli, only a small percentage developed gas gangrene. On further investigation it was found that various substances among them being the ionisable calcium salts, are capable of determining infection if injected into animals along with the detoxicated organisms. The conclusion reached from an exhaustive series of experiments was that the calcium produces a local change in the tissues and the effect of this change is to bring about a local breaking down of the defensive mechanism against *B welchii* To the whole phenomenon they gave the name "defence-rupture" I have merely sketched out the general trend of this work; Gye and Cramer extended it in various directions, and their observations appear to me to open up a very important field of investigation. If this work means anything at all, it is that in infection the state of the tissues is of the first importance Normally we are able to cope with such pathogenic organisms as we happen to encounter but from time to time our defensive mechanism fails, and infection takes place There is evidence that this rupture may be due to some recognisable injury of the tissues but more often, I imagine, it is due to some more subtle change.

FIG 4



High power view of a glomerulus from the kidney illustrated in Fig 3 showing scarring following a streptococcal embolus.

Streptococcus and Calcium.

Bullock and Cramer, in the course of their work, investigated the defence-rupture phenomenon in streptococcal infections as a control to their in an individual of average susceptibility a fairly regular reaction, but any variations in virulence or susceptibility may so modify the inflammatory process as to cause the greatest confusion The histology of tuberculosis, for example, belongs to the elements of pathology, but under certain circumstances the tubercle bacillus causes lesions which may deceive the most experienced histologist Nevertheless, enough facts have already accumulated to encourage the pursuit of this line of investigation Indeed, the very fact that variations in infections are so common should be a further encouragement rather than the reverse, for very often the true understanding of the usual is best obtained from a study of the unusual A very large amount of work has already been done in the direction of modifying the infectious process, but the literature of the subject is so vast that no attempt at any kind of review can be made here.

Experimental Methods of Altering the Host's Reaction

Altering the virulence of the infecting organism amounts to increasing or diminishing the dose of the exciting agent, and is a most valuable experimental method employed by Pasteur in his pioneer work on chicken cholera and anthrax But it is in the behaviour of the host that the answer to the problem lies Two obvious methods of investigating the behaviour of the host in infection suggest themselves One is to break down the immunity to any particular organism of a non-susceptible animal, and then to determine what happens when we infect it with the organism in question; the other is to study what happens when we infect a susceptible animal which has been rendered artificially immune

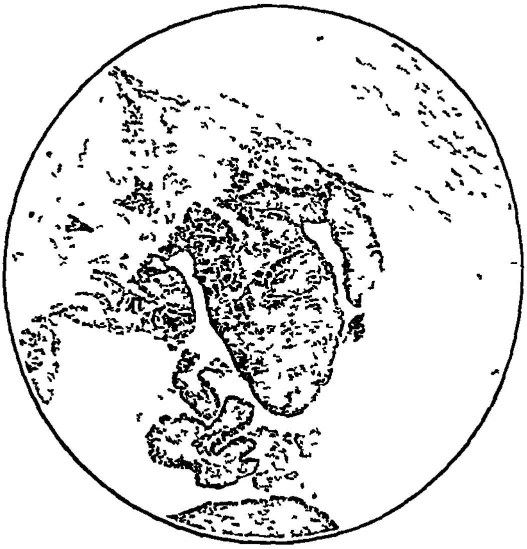
Immunity not Limited to the Body Fluids

Having successfully prepared our experimental animals we must next ask ourselves exactly what it is we are going to study The natural answer would be the blood of the animal, for by most people the study of immunity is limited to that of the body fluids. I do not wish to enter into the ancient controversy between the cellular and the humoral schools of immunity, a working compromise seems to have been arrived at between them and the humoralists have absorbed the wandering phagocyte into their fold But we are entitled to ask whether the blood contains and represents the whole of the defensive mechanism of the individual Is it only a vehicle of inconstant composition, or does it really represent the concentrated essence of the tissues, and can we comprehend the whole process of infection from a study of the blood alone? Except in the rarest instances infection of the blood stream is a purely laboratory phenomenon Infection concerns the tissues first and the blood only secondarily, and it may be that the importance of the blood in immunity has been overrated We are all familiar with the serological phenomena of immunity. Immunisation is undoubtedly accompanied by the appearance of various antibodies in the body fluids, but are these serological changes really a measure of immunity or are they merely a concomitant of it? Further, does the antibody content of the blood serum represent with exactitude the antibody content of the tissue lymph? And does this, in turn, vary in composition according to the powers of resistance possessed by the cell itself?

Modern immunology rests on the tacit assumption that the antibodies of the blood do, in fact, serve as a qualitative and quantitative measure of the state of immunity of the body as a whole If one considers this assumption critically, it is difficult either to prove or disprove it The process of infection is concerned with so many variables that even the most carefully devised experiments are more than likely to give ambiguous results. And the whole trend of work in this subject has for so long been concentrated on the antibodies of the blood that it seems almost presumptuous to doubt their importance. Nevertheless, the tissue cell must be the ultimate source of the protective constituents of the serum

In the immunity produced to toxins we know that the specific antitoxin circulates in the blood and that the immune blood can confer passive immunity if injected into another individual But this is not the whole story Romer showed many years ago that a local immunity to abrin could be developed in the rabbit's conjunctiva without any concomitant development of antitoxin in the serum or in other tissues Again, in the phenomenon of anaphylaxis it has been clearly demonstrated that the site of the reaction is in the cells of the body. Now, just as it is possible to produce passive immunity to toxins, so it is possible to produce passive anaphylaxis, but the animal receiving the sensitised serum only becomes hypersensitive after a certain interval of time The mere drenching of the tissues with a sensitised serum is not sufficient to render an animal anaphylactic; there must be time for the serum to bring about a definite change in the tissue cells

FIG. 2



Section of vegetation on the heart valve in a case of subacute infective endocarditis showing black masses of streptococci

One of the most useful diagnostic methods given to us by immunology is the Wassermann reaction This, as you know, is a logical extension of the Bordet-Gengou phenomenon It was not arrived at by chance but was based on the reasoned application of immunological facts How disappointing is it, therefore, to find that there is really no rational basis for the Wassermann reaction at all It is, indeed, as empirical as any procedure of clinical medicine, and I think one may be permitted a doubt as to the validity of the immunological teaching on which it rested

Another immunological test which has certain anomalous features is the opsonic index This was chiefly established by observations on the serum of patients suffering from tuberculosis and staphylococcal infections The method depends, of course, on the estimation of the phagocytosis by polynuclear leucocytes of organisms which have been exposed to serum Now the polynuclear leucocyte plays a predominant part in staphylococcal infections, but it appears to have no importance at all in the ordinary tuberculous lesion Are we justified in using as our indicator of immunity a cell which plays no part in the progress of the disease in the body? Can the same indicator be of equal value in two such diverse infections? One does not doubt the accuracy of the opsonic index any more than one doubts the accuracy of the Wassermann reaction, but it is permissible to question the validity of the assumption on which it rests are inoculated into the subcutaneous tissues of the mouse an acute abscess forms in a few hours and remains more or less localised The inoculum becomes invaded with polynuclear leucocytes which phagocytose bacilli with great readiness Many of the leucocytes are so packed with bacilli that their nuclei are quite obscured In course of time the centre of the abscess breaks down and bacilli may proliferate in this necrotic zone to some extent But the inflammatory process does not spread, the organisms are eventually destroyed, and healing takes place in the usual way If calcium chloride is inoculated along with bacilli a very different result is obtained I have never seen lesions so extensive as can be produced with streptococci but the diphtheria-calcium lesions are, as a rule, very much larger than the pure diphtheria lesions Further, they differ histologically The initial œdema appears to be even more important to the diphtheria bacillus than to the streptococcus, for the bacilli proliferate enormously and, although leucocytic emigration is pronounced, yet the resulting abscess is never strictly localised Zones of leucocytes packed with bacilli occur, but a fibrinous exudate tends to persist, on the surface of which bacilli proliferate abundantly Indeed, making allowances for the fact that we are dealing with a more or less solid tissue instead of a mucous surface, the whole lesion is strongly reminiscent of the human diphtheritic membrane (Fig 7) It is possible that more toxins are liberated by the diphtheria bacilli than by the streptococci, but we have not, as yet, observed anything which could be called a general toxæmia In our experience, the virulence of the strain of streptococcus employed is not of predominant importance, but different types of diphtheria bacilli do appear to act in different ways Some give rise to much more pronounced lesions in mice than others, and the reaction is not so profoundly modified by the calcium At the same time the importance of a fairly large dose of calcium becomes apparent when dealing with less virulent strains

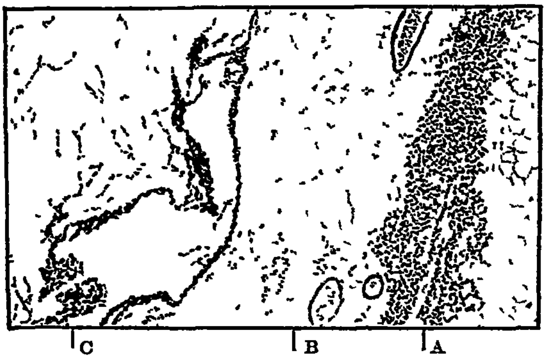
Chart of an experiment showing the determination of streptococci from the blood into early calcium lesions

I do not think it would be justifiable to discuss these experiments in any greater detail at present As you may imagine, even in these preliminary investigations all sorts of interesting suggestions have arisen, and until they have been put to the proof, it would be very unwise to theorise further But I feel sure that the work along these lines must eventually throw valuable light on the process of infection

TUBERCULOSIS AND SILICA MINERS' PHTHISIS

It is quite impossible to be interested in infection without turning one's attention sooner or later to tuberculosis, and, from our point of view, this disease is of peculiar importance It is generally recognised that most of the inhabitants of civilised countries are infected with the tubercle bacillus at some period of their lives, and that most of these infections are successfully overcome, indeed, considering the ubiquity of the tubercle bacillus its pathogenicity is remarkably low Nevertheless, a considerable number of people do die of tuberculosis every year, and this can only happen if there is some modification of what we may call the average infection For the most part we have no conception of the nature of this modification, but the study of industrial diseases reveals one important contributory factor It is well known that individuals who are exposed to dusts containing silica are liable to develop chronic pulmonary fibrosis, and are peculiarly prone to pulmonary tuberculosis, and in the gold-mining industry of South Africa the incidence of this so-called miners' phthisis has been so high as to necessitate a special organisation to deal with it But though it is agreed that silica aids the development of the tubercle bacillus in the human body its mode of action is not definitely known It would take too long to discuss the pathology of miners' phthisis in detail, but we may take it as accepted that silica is a protoplasmic poison, and that when it comes into contact with the tissues it slowly changes into a soluble form and produces its effect by chemical not physical means Fibrosis alone, however, can scarcely render a lung hypersusceptible to the tubercle bacillus, there must be something more in the accessory action of the silica than this Trying to elucidate this matter Dr W E Gye and I compared the lesions produced by inoculating tubercle bacilli together with silica into the subcutaneous tissue of mice with those produced by inoculating the bacilli alone We found that if we added silica to our inoculum the bacilli proliferated enormously in the centre of the necrotic zone, whereas without the silica the organisms remained practically quiescent and gave rise to scarcely any tissue reaction It seemed obvious that this bacterial growth might be due to three possibilities (1) the coagulum might protect the organisms mechanically during the early days of their lodgment in the body, (2) the disintegrated cells might furnish an unusually favourable pabulum, (3) the silica might act as a direct stimulus to the growth of the bacilli In the first two possibilities the silica would act simply by causing necrosis of tissue, but in the third it would act specifically on the bacillus rather than on the host. To test this matter further, I used the technique of the fixation abscess In this method a silica lesion is produced in one flank of a rabbit or mouse, and in the other flank an abscess is brought about by some such agent as calcium or turpentine The animals are then inoculated intravenously with tubercle bacilli, and the lesions are examined in a fortnight or three weeks' time for the presence of the organisms I have found that whereas tubercle bacilli are almost invariably

FIG 7

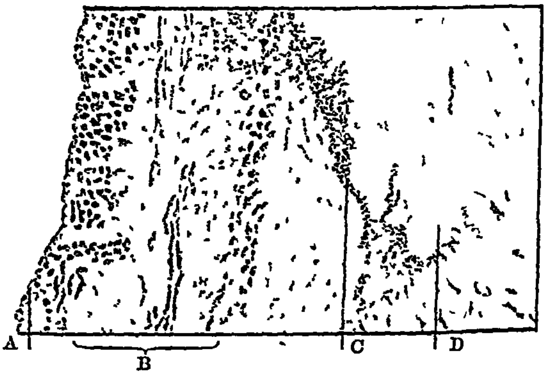


Diphtheritic inflammation in the mouse 67 hours after the subcutaneous injection of diphtheria bacilli and calcium chloride A, External leucocytic zone B, Semi necrotic subcutaneous tissue C, Necrotic zone showing masses of diphtheria bacilli observations on gas gangrene I have repeated some of their experiments and can fully confirm their results.

I have used several strains of streptococci, including one isolated from a normal throat, one from a case of puerperal sepsis, and one from a fatal case of cellulitis and have found them all practically non-pathogenic for the mouse Injected into the subcutaneous tissue they produce a small abscess which remains localised and disappears in three or four days, leaving nothing but a microscopic scar If, on the other hand, calcium chloride is added to the suspension of streptococci a very extensive spreading abscess is produced which invades the body wall and causes ulceration of the skin And whereas streptococci inoculated alone into the subcutaneous tissue of the mouse appear to remain entirely localised, if they are inoculated together with calcium they pass beyond the bounds of the local lesion, for, in several cases, I have recovered them from the heart blood, although I have not succeeded in doing this when they have been inoculated without the calcium At the same time the absolute pathogenicity of the streptococcus is not apparently increased by the calcium, for mice remain healthy with very extensive lesions for periods of a week or even longer What are the essential differences in this reaction? In both the introduction of the streptococcus causes an acute inflammatory reaction, with a profound exudation of polynuclear leucocytes and proliferation of the fixed connective tissue cells But in the streptococcal-calcium lesions the organisms proliferate to a very much greater extent than they do in the pure streptococcal lesions And this does not appear to be due to diminished phagocytosis, for in the calcium reaction there is as abundant an emigration of leucocytes as in the pure streptococcal reaction, and these leucocytes are just as actively phagocytic It would seem rather that the streptococci do not find a favourable medium for their growth in the normal tissue fluids of the mouse In the pure streptococcal lesion the centre of the abscess is necrotic and contains large numbers of cocci But these cocci do not undergo progressive proliferation to any extent; in fact, they appear to die and disintegrate within a few days, for I have tried more than once to produce an exaggerated lesion by inoculating calcium into the flanks of mice bearing streptococcal abscesses at varying times after infection but without success It would seem that the vitality of the organisms in these healing abscesses is rapidly lost In the calcium lesions, on the other hand, the cocci take full advantage of the intense œdema produced by the metal and undergo a remarkable progressive proliferation It is commonly stated that, in acute infections which are being successfully resisted the invading organisms are shut off from the rest of the body by a zone or wall of leucocytes But I am rather inclined to think that this is more apparent than real, for I have repeatedly observed in pure streptococcal lesions diffuse inflammatory foci in which the margins are quite undefined, though it is certain that such lesions are not developing ones Possibly the plugging of the peculiarly large lymphatics of the subcutaneous tissue of the mouse with masses of leucocytes has been mistaken for incapsulation, at any rate, I have seen this kind of thing in the streptococcal-calcium lesions in conjunction with the diffuse cellulitis which is characteristic of this reaction, and, in passing, I may point out that the streptococcal-calcium lesions bear a most striking resemblance to the pure streptococcal cellulitis occurring in the human being (Fig. 5)

I do not think that by simple histological work we shall be able to determine exactly how the calcium modifies the streptococcal infection, the changes are rather too subtle to be appreciated And I have, in conjunction with my colleague, Dr John Mills, endeavoured to throw some light on this question by modifying the experimental conditions in various ways I need not labour the point that the possibilities of experimental error in this kind of work are very considerable, so many factors are capable of accidental variation that each experiment must be repeated many times before one can place very great reliance on the results obtained Our work is really only in its infancy and, therefore, our conclusions are purely tentative There is evidence to show that the actual amount of calcium trauma is a more important factor than the number of infecting organisms introduced or the virulence of the strain used. I have obtained, as a general rule, far more pronounced defence-rupture with larger doses of calcium than with smaller doses, with 10 mg than with 5 mg. And this result does not seem to be due simply to an exaggeration of the initial calcium lesion, it is not, as it were, an expression of the simple addition of the two lesions, because the initial calcium effect would be entirely lost in the massive end-result But it would appear that the more abundant œdema produced by the larger dose of calcium permits of the proliferation of the cocci in situ which determines the severity of the resulting infection Again, the defence-rupture phenomenon occurs, in our experience, more readily in the earlier than in the later stages of calcium poisoning This is illustrated by the following experiment, and is, indeed, in agreement with certain observations made by Bullock and Cramer in their work on gas gangrene (Fig 6). Of 14 mice, 7 were inoculated on one day with calcium into the right flank and magnesium nitrate (which is incapable of producing defence-rupture) into the left flank The next day the other seven mice received similar inoculations, and the following day the whole 14 animals were inoculated into the tail veins with streptococcal suspension The animals were killed at intervals of three or four days, when it was found that, in the first seven, with one slight exception, the only difference observable in the two flanks was obviously due to a pure calcium effect; whereas, in the second seven, three exhibited very pronounced spreading abscesses in the calcium flanks, though nothing of the kind was present in the magnesium flanks, and in two others the same difference was noted, though in a minor degree

FIG 5



Streptococcal cellulitis in the mouse 72 hours after subcutaneous injection of streptococci and calcium chloride A, peritoneal surface B, Muscle of abdominal wall C, Spreading leucocytic zone at the margin of the lesion D, Area of tissue necrosis

Diphtheria-Calcium Lesions

It is possible that the extensive proliferation of the cocci in the early calcium coagulum may permit of the elaboration of a sufficient amount of soluble toxic to modify the infective process; and we, therefore, determined to repeat some of these experiments, using diphtheria bacilli instead of streptococci It is usually stated that the diphtheria bacillus is non-pathogenic to mice and I may say at once that we have not yet succeeded in killing mice with them But at the same time the local reaction produced by this organism is quite as extensive as that produced by the streptococcus If washed diphtheria bacilli

1 The *normal* as stated above, in which the acid curve shows a simple rise and fall, the peak of the curve denoting the point of time at which relaxation of the sphincter occurs

2 *Hypertension or spasm of the sphincter*, in which it acts in the normal fashion in the early stages of digestion, but fails to relax at the appointed time, so that neutralisation does not occur, and the acid curve either maintains its level or continues to rise This is the functional disturbance of the stomach known as hyperchlorhydria, the commonest of all gastric disorders, in which the symptoms appear in the later stages of digestion when the pylorus refuses to relax Several types of this condition exist, according to the action of the pylorus

3 *Excessive relaxation of the pylorus*, in which relaxation occurs from the beginning of digestion, regurgitation and neutralisation commence at once, bile is usually present in the gastric contents, and the condition of achlorhydria is established

At first sight this explanation of sphincter action does not appear to satisfy all demands, for if the pylorus relaxes excessively as in the third condition the stomach might be expected to empty more rapidly than normal, which is, however, not necessarily the case A difficulty is also presented by the class of case in which the stomach empties rapidly and yet neutralisation fails to occur The explanation of these anomalies will be given later

Movements of the Duodenal Contents

To understand precisely the action of the pyloric sphincter is without a doubt the first step in the elucidation of functional disorders of the stomach. The acidity of the gastric contents is quite a secondary consideration, and so long as the sphincter acts normally the amount of gastric juice secreted is of little moment It is thus of first importance that the exact movements of the duodenal contents and the part played by the pylorus in the process of their regurgitation into the stomach should be clearly explained For this purpose a series of 100 cases has been studied and four distinct movements have been observed

1 Contraction of the cap (first part of duodenum)

2 Peristaltic contraction of the duodenum (other than the cap), propelling the contents forwards

3 Contraction of the duodenum (other than the cap), forcing the contents backwards, presumably antiperistalsis

4 Segmentation or mixing movements

These movements have been observed in normal cases, and also in such conditions as gastric ulcer, duodenal ulcer, gall-stones, new growth of stomach, gastro-enterostomy with patent pylorus, appendicitis, and pyloric stenosis

Of these four movements we are in this paper chiefly concerned with antiperistalsis *Antiperistalsis* was observed in 93 per cent of the cases, and is evidenced by swaying or regurgitant movements backwards towards the pylorus It appears to be due to actual contraction of the duodenum and is just like peristalsis, but in the opposite direction The cap contracts and passes the food into the second, and sometimes, the third part, of the duodenum. An antiperistaltic wave is initiated, and sways the food back like a pendulum for varying distances; it often passes back into the cap, which it may distend, and is then held up by the pyloric sphincter, or it may fall short of this point A peristaltic wave propels it onwards again and an antiperistaltic wave returns it If food has in the meantime left the stomach the two portions mix together. There is no rule as to how many times the food mass may thus swing backwards and forwards, the first peristaltic wave may drive it into the jejunum or it may take several waves to force it into this part, but once in the jejunum it does not appear to return to the duodenum The most active antiperistaltic movements occur in the second part, but the food mass may swing back from any part of the duodenum. It may be temporarily held up at the duodeno-jejunal flexure, but not more often than at any other point, and there is no visible evidence of a definite sphincter action at this position In every case the cap is periodically filled or partially filled by antiperistalsis of the duodenum, and the only barrier to regurgitation into the stomach is the pyloric sphincter These movements go on until the stomach is empty, they become less evident as the stomach empties, although at this stage the food tends to be held up for a longer time in the duodenum The peristaltic and antiperistaltic movements apparently occur independently of each other or of the gastric movements They may occur alternately, with a regular rhythm for a time, or quite irregularly This swaying movement must be a more efficient mixing agent than the segmentation movements

Regurgitation into the Stomach

Regurgitation into the stomach was directly observed in six cases only, and this small percentage is no doubt due to the difficulty in detecting the opaque emulsion passing back through the narrow pylorus We are therefore not in a position to speak more positively than as follows Regurgitation only occurs now and then, and certainly not with every antiperistaltic wave This agrees with the fact that the neutralisation is not a rapid process, as shown by the relatively slow descent of the acid curve When regurgitation was observed there was no doubt whatever that the pylorus was relaxed between the gastric peristaltic waves, because the food was seen to pass right back into the stomach through the cap, owing to the impetus imparted to it by the second part of the duodenum Regurgitation into the stomach would no doubt always occur when food regurgitated into the cap, if the pylorus was relaxed at the moment, and provided also that the reflux was not prevented by a peristaltic wave of the stomach So far as these observations go at present there can be no doubt that this is the case The most reasonable hypothesis to advance is that the pylorus commences to relax independently of the gastric peristaltic waves as digestion proceeds, and regurgitation occurs from time to time When the stomach is empty it is well known that the pylorus is relaxed independently of gastric peristalsis, and this relaxation no doubt normally begins before the stomach is empty The conditions in the duodenum are favourable to regurgitation and, if the pylorus relaxes, it is merely a question of difference of pressure in the duodenum and stomach. Marbaix [8] many years ago registered a duodenal pressure of 10 cm. to 15 cm water, and Payne and Poulton [9] in a normal person found the mean pressure to be 14 cm. with rises to 18 to 20 cm With a relaxed pylorus these pressures are quite sufficient to overcome the mean intragastric pressure which is commonly below 10 cm. water, but, since with a peristaltic contraction of the stomach the pressure in the pyloric end rises to 20 cm or 30 cm. water or even higher, regurgitation from the duodenum would be impossible at such a moment

In the present state of our knowledge we must conclude that when the stomach is filled with food the pyloric sphincter assumes its postural tonus and relaxes only before gastric peristaltic waves, when the stomach has emptied to a certain point the sphincter commences to relax also between the peristaltic waves and pyloric regurgitation occurs from time to time, when the stomach is empty the pyloric tonus is low and the pylorus remains open for many minutes at a time, allowing free regurgitation of intestinal fluids A certain amount of leakage no doubt occurs in some cases even in the early stages of digestion, as now and then the curve of inorganic chlorides rises to a certain extent, and we have observed regurgitation within a quarter of an hour after taking food

The pyloric sphincter has thus the two functions of regulating (1) the output of the stomach, and (2) the regurgitation of the duodenal contents The latter is the principle recognised some years ago by Boldyreff from animal experiments These two functions are both disordered together in pyloric hypertension or spasm, when retention of food occurs along with deficiency in the neutralisation of the gastric contents Relaxation of the pylorus between gastric present in large numbers in the silica lesions, they only occur in small numbers in the control lesions, and this, in spite of the fact that the necrosis produced by calcium and turpentine is much more extensive than that caused by silica Simple necrosis of tissue, therefore, is not the explanation

The possibility that silica is a direct stimulus to the growth of the tubercle bacillus may be studied in vitro, and I have made many attempts to enrich culture media by adding various quantities of silica to them, but my results have been too inconclusive to be of much value Similarly I have tried to alter the development of an artificial miliary tuberculosis by treating animals with silica before inoculating them intravenously with bacilli Inasmuch as the same cells, the reticulo-endothelial cells, phagocytose both silica and tubercle bacilli, I thought it possible that if I gave my rabbits a preliminary course of silica intravenously they might react differently when infected with tubercle bacilli by the same route But here again my results have been inconclusive In some animals the silica appeared to cause a pronounced exaggeration of the infection, but in others it seemed to cause exactly the reverse It may be that the preliminary treatment with silica has to be very *carefully adjusted* Too much silica may so poison the cells as to interfere with their phagocytosis of the bacilli, and this is a point which I am investigating at present

As the matter now stands, therefore, we cannot claim that we understand exactly how silica acts in increasing the susceptibility of the tissues to infection with the tubercle bacillus But that it actually does so is beyond all doubt, and in miners' phthisis we have an infection in which the influence of a third or accessory factor is clearly manifest

Conclusion

In conclusion I would suggest to you that inflammation is not a stereotyped process or sequence of changes which occurs in the tissues in response to irritation, but that it is a variable phenomenon which alters its characters according to type of stimulus which calls it forth Different irritants produce different results, and it should be possible to distinguish the nature of the irritant from the type of the reaction And since microbic infection necessarily implies inflammation, it should be possible for us to recognise different types of inflammation corresponding to different groups of pathogenic organisms This being so, it seems highly probable a closer study of microbic inflammation will reveal specific tissue changes which may be of significance in the attempt to combat these infections If we understand exactly why particular bacteria make good their footing in the tissues, and how the tissues respond to their presence, it may be possible for us to devise logical methods of modifying or combating infection It is, at any rate, a line of inquiry which I commend to your notice as having interesting possibilities

I should like to express my indebtedness to my laboratory assistants, Mr Armstrong and Mr Napper, for much invaluable help in the preparation of the material for these lectures

Bristol's Crippled Children—It has been decided to amalgamate the Orthopædic Hospital and Home for Crippled Children of 36 beds, at Redland, and the Bristol Crippled Children's Society A site has been obtained for a new building to provide ample facilities for open-air treatment

Hospitals Contributory Scheme for Birmingham—For some time past the desirability of establishing a contributory scheme has been under consideration at Birmingham The city's hospitals council recently unanimously approved the scheme and it has now been accepted by the Board of Delegates of the Birmingham Hospital Saturday Fund, the organisation of which will continue to be utilised This step is a necessary accompaniment of the pending reorganisation of the hospital service of Birmingham which at present provides a number of beds not only inadequate to the needs of the district but smaller in proportion to the population than in some other great towns

ANTIPERISTALSIS OF THE DUODENUM

AND ITS RELATION TO PYLORIC REGURGITATION

By CHARLES BOLTON, C B E , M D , D Sc Lond ,
F R C P Lond , F R S ,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL ,
AND
R W A SALMOND, O B E , M D , Ch M Aberd ,
HON RADIOLOGIST TO UNIVERSITY COLLEGE HOSPITAL.

Antiperistalsis has not yet been demonstrated to occur as a normal event in any portion of the alimentary canal in man, although it is assumed to occur in the ascending colon from the X ray observations of Cannon [1] and the experimental work of Elliott and Barclay-Smith on various animals [2] The mixing of the food with the bile and pancreatic juice in the duodenum is supposed to be accomplished by segmentation movements after the fashion of the small intestine, and Cannon,[3] describing these duodenal movements in the cat, says that "the to-and-fro movements of the particles may be a relatively extensive and very energetic swinging" Starling, speaking of intestinal segmentation movements, says that "these movements have not a translatory effect, and a column of food may remain at the same level in the gut for a considerable time "[4] Cannon makes no mention of antiperistalsis, and it has not apparently been recorded It appears to us, however, that no other force than that derived from antiperistalsis will explain the movements we describe in the duodenum in this paper The peristaltic movements of the duodenum are very energetic and, if the onward movement of the food is due to them, the same and equally energetic movement backwards may be reasonably assumed to be due to antiperistalsis The study of the movements of the duodenum by the X ray method is more difficult than that of the stomach , and perhaps this is the reason why no important information has been added to the subject since Cole [5] described the duodenal cap He regarded the first part of duodenum as being really a part of the stomach and as acting as a more or less passive reservoir, which receives the gastric contents expelled through the pyloric sphincter, and from which these contents are abstracted by the peristalsis of the second part of the duodenum It is difficult to understand such a method of emptying the cap, and at the present time the generally accepted explanation is that the cap contracts and discharges its contents into the second part of the duodenum The food is then described as passing rapidly through the second and third parts of the duodenum by propulsive peristalsis, being only momentarily delayed whilst it is broken up and mixed by segmentation movements No delay occurs at the duodeno-jejunal flexure and the food passes directly into the jejunum , slight backflow has been described as occasionally occurring from the third to the second part of the duodenum If these are the normal movements of the duodenum it is impossible to understand how duodenal regurgitation into the stomach can occur It was, however, shown by Bolton and Goodhart [6] that regurgitation of duodenal contents into the stomach is a normal event regularly occurring at a definite time, varying in different persons, towards the end of gastric digestion This regurgitation of alkaline material occurs when the curve of HCl acidity of the gastric contents has risen to an approximate height of 0 2 per cent , and the latter are neutralised, the process being usually completed before the stomach is empty This regurgitation they regarded as being entirely dependent upon relaxation of the pyloric sphincter when the acidity has attained its average normal height The acid curve thus imparts information as to the condition of the pyloric sphincter, and this is practically its only value in diagnosis

Action of the Pyloric Sphincter

It was shown that three conditions of sphincter action exist [7]

We opened a little abscess as before We examined the liver very carefully and found two more areas where fluctuation was present and dealt with these similarly They were quite small and all to the right of the falciform ligament and on the anterior surface The left lobe was normal We removed the gauze from the first abscess and led drains down into the abscess cavities, turning up the omentum to the anterior edge of the liver and stitching its free edge to the falciform ligament and parietal peritoneum in such a way as to act as a barrier between the affected area and the general peritoneal cavity The two drains were brought out through stab openings at either side of the original wound, which was completely closed

The patient's cardiac and general condition improved at once, but he was very restless and for some nights delirious His temperature went up for some days to 101° F He then further improved, the delirium stopped, but the restlessness continued Fourteen days after the operation he attempted to get out of bed and his wound, which appeared to have healed, burst open right down to the peritoneum It was sewn up at once with silkworm-gut under general anæsthesia He subsequently stayed quiet, the wound healed rapidly, and he left the hospital a few weeks later

Bacteriological examination of the pus in this case also showed the infective agent to be *Staphylococcus aureus*

The causes of hepatic abscess, as given in a standard text-book of surgery, are, besides trauma and tropical abscess, "*pyogenic infection of the biliary passages or any infective lesion in the territory of the portal vein, such as appendicitis, typhoid fever, or actinomycosis of the cæcum*" Colitis is also mentioned, and some text-books lay stress on the importance of the suppurative pile We have seen, at autopsy, an enormous liver abscess due to *Streptococcus hæmolyticus*, in which the primary focus was an abscess of the lung following pneumonia, infection having reached the liver by direct extension of pus through the diaphragm

In both our cases a careful general examination, paying particular attention to the rectum, was subsequently made to discover the source of infection of the liver, but none was found From the practical point of view, whilst these cases are, of course, very rare, it is obvious that they will not be recognised unless the possibility of their occurrence is borne in mind In the two cases described the symptoms were those of the acute abdomen; in one case the symptoms resembled those of a perforated duodenal ulcer, and in the other they pointed to a suppurative cholecystitis But a study of them failed to furnish anything which would enable us to recognise a given case as being one of acute localised hepatic abscess The operative diagnosis was made, during operation, on (1) omental adhesions, (2) localised swelling of normal-looking liver with underlying fluctuation, (3) the results obtained with the trocar and cannula In Case 2 there was a white plaque on the peritoneal surface of the liver over one of the abscesses The diagnosis in Case 2 was made, practically speaking, by means of the trocar and cannula

The treatment adopted in these cases calls for no comment We cannot dogmatise from two cases about prognosis, but Case 2 proves that even a severe case may recover

---

The late Mr W E Bennett—At the age of 62 Mr William Edward Bennett died on June 4th at his home at Keresley, near Coventry He was a son of the late Mr William Bennett, who built the Royal Opera House, Coventry Studying medicine at the Universities of Birmingham and Paris and at St Bartholomew's Hospital, he qualified as L R C P Lond in 1890, became F R C S Eng in 1895, and graduated as M B at Birmingham in 1902 Before embarking on surgical practice he gained much experience as resident officer at the Queen's Hospital, the General Hospital, and the Jaffray Hospital at Birmingham Many years ago he began to specialise in orthopædic surgery, and at the time of his death was senior honorary surgeon to the Royal Orthopædic and Spinal Hospital, Birmingham He had also been for 21 years surgeon to the Coventry and Warwickshire Hospital, and was honorary demonstrator in anatomy in the University of Birmingham During the late war Mr Bennett held a commission in the Royal Warwickshire Regiment T D, and was visiting surgeon to the 1st Birmingham War Hospital.

AN OUTBREAK OF PARATYPHOID "B" FEVER CONVEYED BY ICE-CREAM

By V F SOOTHILL, M D., D P H. Camb,
MEDICAL OFFICER OF HEALTH, CITY OF NORWICH

With a Clinical Report by G L LEGGAT, M B, Ch.B Edin, D P H,
DEPUTY MEDICAL OFFICER OF HEALTH, CITY OF NORWICH

An outbreak of paratyphoid B fever with 63 diagnosed cases occurred in the city of Norwich, beginning in the month of June, 1926 Its investigation produced some points of interest and the literature concerning ice-cream and paratyphoid fever is not extensive.

The records for enteric fever of the last few years showed, in the summary, in—

	Cases in the first six months	Cases in the second six months
1924	2	9
1925	4	10
1926	10	—

With these figures under consideration on June 30th the possibility of an outbreak was foreseen

Of the latter ten cases the last two are of interest here One, a para B case, was notified from the northern outlying part of the city, with an onset on May 22nd and the origin was untraced, though the usual possibilities (shell-fish, &c) were present As this case occurred nearly three weeks before the outbreak in an entirely different part of the city with no traceable connexion with the outbreak, it is not classed among the 63 cases, but as a sporadic case The other of the two, a case of para B fever, was the first case (S W) of this outbreak, a boy of 11 years with an onset about June 10th

The Outbreak

On June 29th two girls (G T. and A B) were suspected to be suffering from enteric fever This was subsequently confirmed by Widal reactions as para B and their onsets were on June 24th

One of these (A B) was a case of considerable importance The first Widal, taken a little early, was negative; she was very constipated, she had been away to the seaside for three weeks, returning to Norwich on Saturday, June 19th, and there was a certain amount of influenza about She was, therefore, at first considered not to be a case of enteric fever However, a confirmatory Widal was done later, which was positive to paratyphoid B, and she also developed some typical spots Therefore, if she received her infection in Norwich, which was extremely probable, it must have been between her return to Norwich on the 19th and her onset on the 24th Later inquiries showed that on her return to Norwich she had an ice-cream from the infecting source on the 19th, on her way from the station to her home. This fixed her incubation period at five days very accurately On the 30th several cases of an uncertain nature were reported to me and Widal specimens were taken on the appropriate dates These proved to be practically all positive A circular letter was sent to the practitioners of the city calling attention to the outbreak

Notifications were received as under Week ending June 26th, 1; July 3rd, 1; 10th, 25, 17th, 14, 24th, 12; 31st, 7; August 7th, 1; 14th, 2

All the cases were confirmed by positive Widal tests by Dr G P C Claridge, who used living cultures, and throughout this outbreak took as his standard a dilution of 1 in 40 with a time limit of two hours The disease in most cases was very mild, so that it is very likely that there have been some missed cases In fact, some were discovered by accident at the school clinic late in the disease, the diagnosis being confirmed by a Widal test There were no deaths peristaltic waves may occur from the beginning of digestion, giving rise to the presence of bile in the stomach and achlorhydria, whilst the function of controlling the output of food remains normal and the stomach does not empty at an abnormal rate Here is the explanation of the anomaly mentioned at the beginning of this paper that excessive regurgitation my occur, although the stomach does not empty more rapidly than normal The second anomaly—namely, that the stomach may empty very rapidly and yet the acid curve continue to climb and the contents remain unneutralised—also receives an explanation, for, although the pylorus may be of low tone, yet when the stomach empties very rapidly the duodenal conditions are unfavourable to regurgitation, owing to the rapid rush of the food through the duodenum

Summary

1 Antiperistalsis is a normal movement of the duodenum Its effects are to delay the food in the duodenum, to ensure its admixture with the digestive juices, and to produce conditions favourable to regurgitation into the stomach

2 The duodenal cap is filled periodically from the duodenum, the pyloric sphincter preventing regurgitation into the stomach

3 In addition to its function of regulating the output from the stomach the pyloric sphincter prevents regurgitation from the duodenum in the early stages of digestion, as digestion proceeds it commences to relax independently of gastric peristalsis, promotes regurgitation, and thus regulates the acidity of the gastric contents

4 An actual swing back of food from the second part of the duodenum is not always necessary to produce regurgitation, since a full cap with a momentary relaxation of the pylorus will produce it as we have observed

TWO CASES OF
ACUTE HEPATIC ABSCESS TREATED BY OPERATION.

BY T J D LANE, M D DUB, D T M & H LOND,
SURGEON TO THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY, SURGEON, EXTERN DEPT, NATIONAL CHILDREN'S HOSPITAL, DUBLIN,

AND

T A AUSTIN, L R C P & S IREL,
D T M & H LIVERP,
EAST AFRICAN MEDICAL SERVICE

THE two following cases were met with at the Meath Hospital and County Dublin Infirmary within a few months of each other —

CASE 1 —A boy, aged 12, with a well-nourished and well-developed body, was admitted complaining of sharp, severe pain in the upper abdomen, which had come on suddenly a few hours before It hurt him to move about in bed or to breathe deeply or to cough His pulse was 100, his temperature 99° F His bowels had moved on the previous day and he had not vomited For a fortnight before the night of admission he had had occasional vague pain in the belly but he had taken little notice of it and had not gone to bed

On *examination* his abdomen was found to be rigid and immobile, especially in its upper part, there was marked tenderness about the umbilical region The tongue was furred, the pulse fairly good, and the lungs normal Generally speaking, the case was not unlike one of perforated duodenal ulcer.

At *operation* the omentum was found adherent to the duodenum and liver Its free edge had turned upwards and was wedged between, and adherent to, these organs It seemed at first that a perforated duodenal ulcer had been sealed over by the omentum, but on separating the omentum from the duodenum, which was easily done, it was found that the duodenum was intact and quite healthy We then proceeded to separate the omentum which was still adherent to the liver, and were surprised to see a bead of pus oozing from the surface of the liver which had been covered by omentum The pus was wiped away and in the liver we saw a small hole with necrotic edges, on pressing near this hole more pus came out A closed artery forceps was passed in through the hole, its blades were gently opened, and the pus came out freely The abscess cavity was about three-quarters of an inch deep by half an inch wide It was on the inferior surface of the liver close to the anterior edge and in the left lobe The liver immediately around the abscess seemed to be in every way normal

A soft rubber tube was passed into the cavity The omentum was first twisted round the tube and then the tube was brought out through a hole in the omentum, a point or two of fine catgut being employed to keep the omentum in place The tube was brought out through a stab wound 1 inch to the left of the middle line The abdominal wound was closed in the usual way Convalescence was uneventful Pus discharged through the wound for four or five days, the laparotomy wound healed by first intention, and the boy left hospital quite well in three weeks Microscopic and cultural examinations of the pus showed the presence of *Staphylococcus aureus*

It was fortunate that this was our first case of the kind The adhesion of the omentum to the liver led us straight to the trouble, and operative diagnosis was easy to establish We were able to recognise the lesion in the second case only because we had the first one fresh in our minds

CASE 2 —A man, aged 29, was admitted to the Meath Hospital at midday He was very cold, with a subnormal temperature and an all but imperceptible pulse, his face was yellow, pinched, and haggard, his lips were blue He was able to give very little account of himself, but stated for the last 24 hours he had severe continuous pain in the right hypochondrium He had vomited any food he had eaten, his bowels had moved That morning the pain had become intolerable and he came to hospital He had not been feeling well during the previous week

On *examination* the abdomen was found rigid and immobile especially in its upper part, and there was marked tenderness over the gall-bladder area The lungs and urine were normal He was diagnosed as suffering from an acute abdominal complaint, probably suppurative or gangrenous cholecystitis Owing to his collapsed condition, we waited for some hours to allow a rectal saline, morphia, digitalin, and hot-water bottles to improve his condition

Operation —The belly was opened through a right paramedian incision and revealed at once a normal gall-bladder The lesser omentum was bile-stained near its hepatic attachment The peritoneum, appendix, duodenum, stomach, spleen, and colon were all rapidly examined and found normal though slight enlargement of the spleen was noted When examining the gall-bladder we noted a circular white patch about half an inch diameter, flat, and not raised above the surface, on the anterior surface of the adjacent liver On re-examination of this patch we came to the conclusion that it was a peritoneal scar, though it had a superficial resemblance to a Farr's tubercle

We examined the liver carefully, primarily for malignant disease, but also with Case 1 present in our minds Just to the right of the falciform ligament, on the anterior surface of the liver, there seemed to be bulging of the organ, localised midway between the bare area and the anterior edge It was under the ribs The bulge appeared to be about 2 inches in diameter, and we thought that fluctuation was present Accordingly we dragged the liver gently down and had a look The tension on the liver smoothed out the bulge we had felt, and the surface of the suspected area was in no way different to the surrounding surface, but on inserting a trocar of moderate size pus escaped from the cannula We packed off the area and opened the abscess by the Hilton technique It was near the surface and there was very little hæmorrhage but a great deal of pus We plugged the cavity with a sponge and had another look at the scar We tested it for fluctuation and were doubtful We tested it with the sterilised trocar and a little pus escaped exception of four cases (M. M., K. C., H. C., and Mrs. K.) M. M. and K. C. admitted having had some of the ice-cream, though not for about four to six weeks before their onset, but they passed the stall daily on their way to and from work, and their history did not appear to be very reliable. In many cases the incubation period was very short, down even to a one-day doubtful possibility, but none were as long as 4–6 weeks with these possible two exceptions. They, moreover, had had some milk from the "X" dairy. This raises a very interesting question as to whether "X" 1 was temporarily slightly infected by the ice-cream he had eaten, but, owing to his T.A.B. inoculation ten years before, was able to resist it. The fact that his Widal was at first considered by an experienced bacteriologist to be positive suggests the possibility that his agglutinating powers, already in existence owing to his previous inoculation, had received a slight stimulus, but not sufficient to produce a lasting positive Widal. This can, of course, only be a matter for speculation.

• H. C. is a young girl of 16, who very positively denied having had any of Mrs. "A's" ice-cream, and we could trace no connexion at all. However, she agrees to passing the stall occasionally, but in any case she started rather late in the outbreak and may well have been a contact with some other case, known or unknown. She worked in a factory where one other case worked.

Mrs. K.'s onset was July 27th. It is very doubtful whether she ought to be included in the outbreak or considered as a sporadic case. She had never had any ice-cream from the neighbourhood of stall "A": she had had ice-creams, &c., elsewhere, and she had not been in contact with any known para. B cases.

Origin of Carrier State

There is no evidence to show where Mrs. "A" got her infection or how long she has been a carrier. She denies having had the disease. She is, however, fond of shell-fish and she may have received an intermittent infection from this which raised her agglutinating powers and left her infectious. None of the "A" household contracted the disease, although "A" 1 and "A" 2 ate large quantities of the ice-cream. It is possible that the method of making the ice-cream accounts for this. The milk used was subjected in the evening to a crude pasteurisation process and the ice-cream mixture heated. This would be more or less sterilised for non-sporing organisms. The freezing was done next morning and care has to be taken not to let the freezing mixture come in contact with the ice-cream, or else the salt spoils the flavour. "A" 1 and "A" 2 naturally helped themselves, and so might remain free, but Mrs. "A" would handle freely the cornets and wafers. This is again only speculative.

In tracing contacts efforts were made to investigate those people having connexion with food, such as cases from a sweet shop or from a fish shop selling ready boiled shell-fish, &c. In those cases Widal tests and stool and urine examinations were made throughout the household. The stools and urine were examined before a case was discharged from the hospital to such a home, to a food factory, and also in the case of married women who would have to cook on their return home.

We were fortunate in many ways in this outbreak. In the investigation a very severe thunderstorm on June 16th helped many of the cases to fix their dates. Ample accommodation at the isolation hospital once again proved its value.

CLINICAL REPORT BY G. L. LEGGAT.

The outbreak of paratyphoid B fever which commenced in June, 1926, in the city of Norwich totalled 63 cases; 48 of these cases were admitted to the isolation hospital; the discovered carrier, a suspected carrier, and a five days old infant (born whilst its mother was suffering from paratyphoid), were also accommodated at the hospital for a time. Most of the cases were seen in their own homes before admission to hospital, and an opportunity was thus given of observing them at an earlier stage than is usual in hospital practice.

The first two cases of the series were admitted on Tuesday, June 29th, and further admissions were as under:—

July 4th	2 cases	July 20th	3 cases
" 6th	2 "	" 21st	2 "
" 7th	5 "	" 22nd	1 case
" 9th	4 "	" 23rd	2 cases
" 10th	3 "	" 24th	1 case
" 11th	1 case	" 26th	1 "
" 13th	5 cases	" 27th	2 cases
" 14th	2 "	" 29th	1 case
" 16th	3 "	" 31st	1 "
" 17th	2 "	Aug. 1st	1 "
" 19th	2 "		

The age and sex distribution of the cases was as under:—

Year—	2–3	3–4	4–5	5–10	10–15	15–20	20–35	Over 35	Total.
Male ..	—	1	—	6	1	2	—	—	10
Female	2	4	—	8	8	11	3	2	38
Total ..	2	5	—	14	9	13	3	2	48

Seventy-five per cent. of the total cases occurred between the ages of 5 to 20. The proportion of female cases is very striking—practically 80 per cent.

The figures for the period 10–20 years—three males and 19 females—rather tends to confirm the idea that whilst a young girl spends her odd coppers on sweets or ice-cream, the youth of the same age, before as well as after leaving school, spends his on cigarettes!

Incubation Period.

The incubation period was short, in the majority of cases apparently not exceeding ten days. An accurate figure was not possible in many of the cases—a considerable number were young children, whose information could not be relied on; further, many cases had eaten ice-cream frequently from the infecting source, and the true moment of infection could only be a matter of conjecture.

In 19 of the 48 cases the incubation period can be accepted as definite, and an analysis of these 19 cases gives the following result:—

Incubation period.	Cases.	Incubation period.	Cases.
5 days ..	3	10 days	1
6 " ..	5	11 "	4
7 " ..	3	12 "	1
8 " ..	1	18 "	1

Onset.

The onset was distinctly abrupt in character; most of the cases were compelled to take to bed within a day or two of their first symptoms. The abruptness, accompanied by a sequence of symptoms of which headache, lassitude, muscular or joint pains, shivering, and abdominal discomfort were the most prominent, accounts for the fact that many of the patients attributed their condition to either "influenza" or a "chill" on the bowel. The insidious onset usually associated with the enteric group of fevers was decidedly exceptional.

Type.

The type of disease was definitely mild: the period of pyrexia in many cases was not prolonged beyond ten days and the degree of constitutional disturbance was not very marked.

The 48 cases may be grouped as under in their degrees of severity:—

Severe attack	7 cases.
Average "	8 "
Mild "	33 "

Of the 7 cases grouped as severe 4 were in the age-group 15–20; one was 9 years of age, one 12 years, and one 26 years.

Symptoms and Signs.

The majority of these may be dealt with briefly in tabular form:—

Headache: Present in varying degree in practically every case.
Vomiting. In 15 cases.
Muscular pains: 12 cases.
Epistaxis 13 cases.
Abdominal tenderness: 30 cases
Diarrhœa and constipation were present in 22 and 18 cases respectively; in two instances definite slough was passed.
Lassitude. In 30 cases.
Shivering: 7 cases.
Abdominal pains: 25 cases.
Cough: 7 cases.

Tracing the Infection

It was soon recognised that all the cases were coming from one comparatively small area in rather a poor part of the city A little spread occurred later, owing to visiting Moreover, Dr. Leggat was early impressed with the fact that the great majority of the cases were young girls and this, coupled with the hot weather at that time, made him suspect ice-cream An inquiry sheet showing the suspected articles of diet and inquiry amongst the cases in the isolation hospital tended to confirm this, and implicated a certain ice-cream stall, "A," recently set up in the middle of the affected district On July 6th I stopped the sale of ice-cream from the stall "A" However, not all the cases gave a history of ice-cream from this stall In particular three girls (M M, K C, and D B) denied it, but M. M and D. B gave a history of ice-cream from other supplies, shop "B" and barrow "C" On inquiry, stall "A" got the milk for making ice-cream from a certain dairy, "X," and so did shop "B" and barrow "C," and dairy "X" supplied some milk to the household of the girl K C. Therefore dairy "X" appeared to be implicated, and I visited it on July 6th I found a man and wife (Mr and Mrs "X") with four sons ("X" 1, "X" 2, "X" 3, "X" 4), a hired lad, "X" 5, and a serving girl, "X" 6, working the dairy "X" 2 had a decided attack of jaundice when seen on July 6th and gave a history of being off colour a fortnight before to such an extent that he had gone once to his doctor, but had continued as a roundsman Although jaundice is only rare in enteric fever, I stopped him from work until further investigations could be made, but I did not feel justified in closing the dairy At my request Dr W P Yetts was sent from the Ministry of Health on July 7th to assist in the investigations, I am very greatly indebted to him for his advice and help, which were invaluable

Stall or Dairy?

Thus far, the two probable sources of infection seriously suspected were stall "A" and dairy "X," but in the meantime, all the cases then being notified were throwing more emphasis on stall "A" to the exclusion of all other sources

A Widal test and bacteriological examination of the stool and urine of each member of the "X" household showed that —

Mrs "X" had a negative Widal and urine, but her stool contained non-lactose fermenters which gave para B sugar reactions but did not agglutinate with the para B serum

"X" 1 had a slightly positive Widal—i e, one hour in 1 in 40 This was complicated by the fact that he had been inoculated in 1916 with T A B as his army pay-book showed His stools were also examined The first stool examined showed nothing abnormel, but a further stool, obtained by calomel and mag sulph, showed the presence of non-lactose fermenters which agglutinated with para B serum

"X" 2, the son who had the jaundice and previous indisposition, had a negative Widal with a negative urine, but his stool showed the same non-lactose fermenters as Mrs. "X."

Mr "X," "X" 3, "X" 4, "X" 5, and "X" 6 all had negative Widals, stools, and urines

The fact that non-lactose fermenting organisms with the correct sugar reactions of *B paratyphosus* B did not agglutinate with para. B serum had to be discounted to some extent, owing to the opinion, expressed in many books, that true organisms if *recently* isolated might fail to agglutinate with the appropriate serum, so that these organisms in spite of non-agglutination might have been para B bacilli and the cause of the outbreak However, there has been no evidence in this outbreak of this failure of agglutination in newly isolated organisms "X" 1 was removed to the isolation hospital for observation, Mrs "X" and "X" 2 were requested to leave the dairy premises entirely, which they did as the alternative to having the dairy shut down altogether; the dairy was thoroughly cleansed and everything which could be boiled, including glass milk bottles, was boiled, and such utensils as brushes were burnt. Notices to Mrs. "X," "X" 1, and "X" 2 were served under the Public Health (Pneumonia, Malaria, Dysentery, &c) Regulations, 1919.

Home Visits.

Visits were made to the farm supplying the majority of the milk to the dairy and a Widal taken of every member of the household and all the farm personnel, consisting of seven hands, who came into any contact with the milk, and all were interrogated as to their previous history The dairy farm was also examined and the water tested However, all the personal histories, the Widals, and the water tests proved negative and the farm had to be considered free Moreover, inquiries showed that para B had not been in the district for some years In the meantime further cases were occurring and the histories obtained pointed more strongly to stall "A" and the investigation of that was started as soon as possible. Inquiry into the household showed the presence of Mr and Mrs "A," a daughter "A" 1, and a young female shop assistant, "A" 2 Mrs "A," previously a public-house keeper, started to make and retail from Easter, 1926, ice-creams chiefly as halfpenny cornets and penny wafers from a stall outside their small drapery shop, with also a small trade in lemonade and wrapped confectionery The family history of the "A" household showed that Mr "A" had 30 years previously had some enteric fever called typhoid fever, but none of the others had ever had any such disease However a Widal test and a stool and urine examination of every member of the stall "A" household was done. All were entirely negative to T.A B except Mrs "A," who had a positive Widal to para B (half an hour in 1 in 40 dilution) with stools full of non-lactose fermenters giving the sugar reactions of para B and agglutinating with para B serum Therefore she was removed to the isolation hospital, and we felt confident she was the source of the outbreak as, on being questioned, "X" 1, who delivered the milk to the "A" household, remembered having on one occasion eaten ice-cream from Mrs "A," so that, even if dairy "X" were implicated, Mrs "A" might still be the originator of the outbreak The prompt cessation of the outbreak fully confirmed this

Release of the Dairy

However, blood for a Widal and a sample of stool and urine from "X" 1, and cultures of the suspicious non-lactose fermenters obtained from other members of the "X" family had in the meantime been sent to the Ministry of Health bacteriological laboratory and they were all returned as negative with regard to para B As a fact the first specimen of stool from "X" 1 sent to the Ministry had been obtained by means of calomel and mag sulph, and this proved sterile, an interesting point However, other specimens contained the non-lactose fermenters It was reported by the Ministry laboratory that these were not para B organisms and that the "X" 1 Widal agglutination was so slight as to be negative Therefore the control of the "X" dairy was released on July 20th. Two subsidiary supplies of milk to that dairy and the complete list of customers divided into separate rounds were about to be investigated when the arrival of these negative results removed the necessity, from the point of view of this outbreak

The first case of the outbreak was notified on June 22nd with its onset on the 10th The last case was notified on August 9th, with its onset on July 27th The last case was discharged from the isolation hospital on Sept 7th The carrier, Mrs "A," was discharged on Sept 14th, though still an active carrier, as she was very depressed, requiring alcohol and bromide She was served with a notice under the Public Health (Pneumonia, Malaria, Dysentery, &c) Regulations, 1919, and given explicit instructions

The Ice-Cream Stall

Of the 63 cases of the outbreak all were found to have had some ice-cream from stall "A" or to be immediate contacts of such proved cases, with the more extensive hæmorrhage should have occurred and it is difficult to understand why it did not. The second case appears more remarkable. Osler mentions that rupture of the spleen may occur from the breaking of an infarct but adds that the symptoms are those of hæmorrhage into the abdomen. Here, however, there were no symptoms of hæmorrhage into the peritoneal cavity, and the patient lived for nine days after the injury. A further point in this case is that the spleen, though much enlarged, was not palpable below the costal margin Where spleens are large and tempers uncertain, rupture of the spleen is not uncommon: but usually there are definite signs These two cases illustrate difficulties which may arise and are instances of the treachery of abdominal complaints in mental patients

I am indebted to Dr W. F. Samuels the medical superintendent, for permission to publish these cases

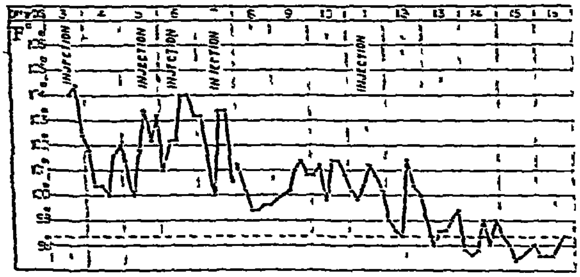
A CASE OF LOBAR PNEUMONIA

TREATED WITH OIL OF TURPENTINE

BY J CHRISTIE-ANDERSON, M.B. ABERD, L.D S. R.C S ENG.

IN cases of pneumonia I have for some time been using a 10 per cent. pure oleaginous solution of rectified turpentine, prepared according to the formula of Prof. Viktor Klingmüller. The dose I have given is 1 to 3 c cm. in adults, ½ c cm in children, intramuscular injection. In no case has there been any irritation or abscess-formation at the site of injection but caution is necessary with this drug, as nephritis has been recorded after its use in children. The following is an illustrative case.

I was called to see a man aged 24, whom I found suffering from lobar pneumonia at the right lower lobe. It was the third day of the disease, there was rusty sputum, and the temperature was 104 2° F. Within an hour I injected 1 c.cm of the turpentine preparation and ordered the usual stimulants The subsequent course of the disease is shown in the chart which indicates the favourable influence of the injections (all of 1 c.cm.) The third was given at a time when the patient was very much distressed, and the effect appeared to be remarkable



On the eighth day of the illness the crisis might be expected and there was in fact a fall of temperature. But this was not maintained and on the eleventh day I gave another injection with satisfactory results.

It will be seen that after each injection there was a marked remission of temperature; the drug seemed to relieve the distressing clinical manifestations enough to allow the patient to battle afresh In a number of other cases also in broncho-pneumonia and bad cases of bronchitis, I have had similar experience of the treatment

---

RADCLIFFE INFIRMARY'S CONTRIBUTORY SCHEME.—Last year 60 per cent. of the total income of this Oxford hospital was provided by the Contributory Fund which amounted to £27,000 The Fund covers a radius of 20 miles from the city, the membership is approximately 70 000, and there are 344 affiliated hospital committees. The out-patients clinic for nervous disorders has been successful enough to warrant the closing of an entire ward in the Littlemore Mental Hospital.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

AT a meeting of this Section, held on June 1st, the chair being occupied by Mr. V. WARREN LOW, its President, a discussion on the

TREATMENT OF CLEFT-PALATE BY OPERATION

was opened by Sir JAMES BERRY, President of the Society, and Mr G. GREY TURNER (Newcastle-on-Tyne).

Sixteen years said Sir James Berry, had elapsed since the Section had last debated this subject, and he invited all who had had experience of cleft-palate operations to relate their results In the earlier debate discussion mainly turned on the comparative values of the turn-over flap and the lateral approximation of the edges of the cleft. In this comparison age was an important factor. Practically the sole object of operating on cleft-palate was to make possible intelligible speech: few if any surgeons now maintained that the operation was undertaken to save life. Yet it was true that an infant with cleft-palate, being unable to take the breast, might die of inanition, although swallowing was not interfered with by the cleft Such an infant should first be carefully fed: there should be no thought of immediate operation which entailed risk from loss of blood and possible sepsis A certain proportion of clefts were very narrow and affected only the soft palate or a part of it; they could often be closed by lateral approximation within a few weeks of birth if so desired. With most clefts, however this was impossible on account of the width of the gap and the lowness of the palatine arch There was a tendency for a cleft of the soft palate, wide at birth, gradually to become narrower; this sometimes happened even if the cleft extended to the hard palate Closure was more rapid when the accompanying hare-lip had been dealt with, as it always should be, within the first few months of life. If an operation was imperative in early infancy for extensive cleft it must be by the turn-over method. The use of wire for forcibly approximating the jaw bones was open to serious objection.

Operation should be undertaken, Sir James Berry continued, at the earliest age which gave a chance, in the surgeon s own experience, of closing the cleft by lateral approximation. His own choice was between 1½ and 4 years of age. A surgeon with less experience would do well to wait until a much later age in the patient's life. Otherwise there was a risk of leaving the palate in a condition which offered less chance of completely remedying the defect later owing to scarring and loss of tissue. Since the earlier debate on the subject he had himself in a number of cases attempted closure at an earlier age than was his former custom, but he was not pleased with the venture, for part of the hard palate had remained unclosed, needing a further operation. Not much was gained, he thought by closing the soft palate at an early age and leaving the hard palate to be dealt with at a later period, when the presence of scar tissue rendered it more difficult to separate the soft tissues from the posterior edge of the bony palate. The most difficult cases, he had found were those in which the cleft was very wide and involved the soft and most of the hard palate, and in these he elected to close the cleft in the soft palate first leaving the hard palate for a time It was often better to leave the anterior end of the cleft unclosed rather than endanger the vitality of the flaps by severing the anterior palatine artery. The small hole remaining might close spontaneously, or require at most a small subsequent operation. Greatest importance attached to closure of the soft palate: a patient was but little benefited if the rent in the hard palate was closed and that in the soft palate remained open No obturator was as good as a well-restored soft palate

The following clinical notes are perhaps of special interest —

The *abdominal reflexes* were studied in all patients; in the severer cases they were usually absent; late in these severe cases, and in those of a mild type, their presence or absence was extremely variable, one feels that too much stress must not be given to this side

The *Diazo reaction* in the urine was carried out in all cases, in 26 of the 48 cases it was found to be positive

Spleen —Examination gave the following results *Palpable* definitely in 18 cases, and in 6 of these appreciably tender to the patient. In several of the youngest children the enlargement was pronounced Enlargement *on percussion* was noted in eight other cases, and *tenderness* only, on palpating the splenic region, was elicited in six cases Therefore in 36 of the 48 cases some degree of splenic abnormality was detected This may seem a high proportion, but, as pointed out earlier, most of these cases were seen prior to admission and at an earlier stage than is customary in hospital practice

Rash

In 37 of the 48 cases the rash was present The rash varied in intensity from a few scattered spots to a succession of profuse crops In many cases the typical spots were seen when the patients were visited in their own homes, this high proportion showing a rash inclines one strongly to the view that the rash of paratyphoid B fever is possibly present in all cases at some period during the course of the disease

Wasting was quite appreciable in 20 cases, and in five of these it was severe

Complications.

Hæmorrhage and perforation Nil

Thrombosis. Three cases—one of the left femoral and two of the right popliteal vein

Boils occurred in two cases

Relapses Eight patients relapsed—in four of these cases the relapse commenced before the primary attack had terminated, in three within a week, and in one after an interval of a fortnight The primary attack was severe in two of these cases, average in two, and mild in four. The relapse in all cases was mild in character One of the cases with *thrombosis* developed this condition during the course of her relapse

Treatment —The cases were all treated on expectant lines and the dietary from the commencement was liberal

Clinical and Laboratory Notes.

HYPERTROPHY OF THE TONSILS IN LYMPHATIC LEUKÆMIA

BY F STOKER, M B DURH, F R C S EDIN,
SURGEON IN CHARGE OF THROAT AND EAR DEPARTMENT, QUEEN MARY'S HOSPITAL, AND THE ITALIAN HOSPITAL, LONDON

Lymphatic leukæmia, though recognised as a cause of tonsillar hypertrophy, is not commonly given as such in the text-books Yet the importance of appreciating this association is obvious, for the operative removal of leukæmic tonsils must lead to disappointment, or even to disaster The following case may be looked upon as of the type likely to be referred to the surgeon, though the patient had attained a more advanced age than is usual in this disease

A man, aged 55, was referred to the throat department of Queen Mary's Hospital for investigation of a possible cause of enlarged glands in both anterior triangles He had lost weight, was sallow in complexion, but complained of no symptoms The glands were only moderately enlarged, three masses as large as green almonds being in both anterior triangles They were not hard nor in the least tender, were painless and freely movable The soft palate and anterior pillars were of a dusky reddish hue, and the pillars were stretched over the tonsils Both faucial and lingual tonsils were markedly hypertrophied, the hypertrophy was symmetrical and disposed in a lobulate fashion, particularly in the lingual area The hypertrophied parts were yellowish-grey tinged with violet in colour, and looked friable, almost suggesting sarcoma to the cursory eye, on palpation they were firm and of the resiliency of quarter-inch rubber tubing The pharyngeal and Eustachian tonsils were not involved, nor were any other lymphoid follicles in the mouth or throat

A piece of the right tonsil was taken for microscopic examination, and Dr Arthur Davies reported that "the outer lining membrane of the specimen consisted of stratified epithelium, the deepest layers of which were regular, and showed no tendency to transgress its normal limits Subjacent to this epithelial lining was found lymphadenoid tissue occupied by masses of cells resembling leucocytes The blood-supply was not abnormal. The usual picture of the tonsil germ centres was not as marked as was usual on account of the dense aggregations of small round cells There was no evidence of a malignant process A blood count might afford useful information"

Dr J Standish did a blood count and reported as follows hæmoglobin, 85 per cent, red cells, 4,320,000, colour-index, 1; total white cells, 168,000, polymorphs, 6 per cent, eosinophils, 0, mononuclears, 2 per cent., small lymphocytes, 92 per cent

The diagnosis appears to rest on the absence of symptoms, the symmetrical hypertrophy and its appearance, the painless enlargement of freely movable and elastic glands, and particularly upon the blood count I should like to take this opportunity of expressing my gratitude to Dr Davies and to Dr Standish, pathologists to the hospital, for the assistance given to me

TWO FATAL CASES OF UNSUSPECTED RUPTURE OF THE SPLEEN

BY F. WILSON, M B ABERD,
ASSISTANT MEDICAL SUPERINTENDENT, CENTRAL MENTAL HOSPITAL, TANJONG RAMBUTAM, FEDERATED MALAY STATES

IN the following cases rupture of the spleen occurred without producing definite signs of an abdominal accident.—

CASE 1 —A Chinese male epileptic, aged 17, had a series of seizures on June 23rd, 1926, and passed into status epilepticus On examination his pulse was regular, 80 per minute, and with good tension The spleen was palpable, about two fingers-breadth below the costal margin No rigidity or tenderness on pressure was noted An enema was given, followed by chloral and bromide per rectum. The seizures stopped, but the patient remained in a semi-conscious condition till the morning of June 26th, when he died

At autopsy a considerable amount of faintly blood-stained fluid appeared when the peritoneum was opened The spleen was soft, enlarged, weighed 20 oz, and showed malarial pigmentation On the lower surface there was a rupture 2½ in. long and ¼ in deep filled with a semi-organised blood clot which surrounded almost the whole spleen There was marked congestion of all the organs

CASE 2 —On August 24th, 1926, a Chinese male dement, aged 55, was admitted into the infirmary ward complaining of pain in the left hypochondrium The history given was that a log had fallen on him while he was lifting firewood He had a few abrasions on the lower extremities but no marks of injury on the abdomen Nothing suggested an abdominal accident Two days after admission all pain had disappeared, he was eating and sleeping well, and was allowed to move about

On Sept 2nd, nine days after admission, he again complained of pain, and was seen at 7 A M. by the senior assistant physician who noted that the pulse was 100 per minute, but of quite good tension, the temperature was 98 4° F, and on palpation no tenderness, rigidity, or enlargement of the spleen was evident The patient was seen afterwards by myself and another colleague His pulse was then 110 per minute, but our examination confirmed the notes previously made Nothing suggested an abdominal catastrophe, and the spleen was not palpable The patient died quite suddenly at 11 30 A M on the same day

Post-mortem Examination —The spleen was enlarged, weighing 24 oz, but did not appear below the costal margin On section numerous infarcts were seen of varying age One recent infarct on the lower surface, about 2 in in diameter, had ruptured, as also had the capsule over it From this point a large semi-organised blood clot spread under the capsule for a short distance and surrounded the whole of the lower surface of the spleen The peritoneal cavity contained a small amount of straw-coloured fluid but no trace of fluid blood was seen Apart from the spleen, the only abnormalities noted post mortem were marked arteriosclerosis and amyloid degeneration of the liver, both probably of syphilitic origin

In the first case the rupture probably occurred as the result of a fall in a seizure, and the presence of status epilepticus was not helpful to diagnosis The general congestion of the organs suggested that a was deficient the Langenbeck method gave the better result.

Mr. H. D. GILLIES made some remarks on secondary operations The great majority of cases, he said, would be vastly improved by severing the soft from the hard palate, making provision for an epithelial covering of all raw areas, interposing an appliance between the soft and the hard palate, and allowing the soft palate to assist in shutting off the nasal from the buccal cavity.

Mr C H FAGGE said that up to the end of 1924 he had operated 218 times on 114 cleft-palate patients, some of these operations were on the lips, others for closure of holes in the palate On the largest group of cases, those of complete unilateral cleft, he first performed a Lane's flap operation on the hard palate, then a hare-lip operation, and finally closed the soft palate at a second sitting He had never failed to close a hard palate with a Lane's flap, nor had he seen one break down Lane's operation did not make the operation on the soft palate any more difficult. He had an impression that whenever he could close both the hard palate and the soft before the first dentition commenced he would obtain a good anatomical result With the Langenbeck operation pure and simple he had had about 60 per cent of successes and 5 per cent of complete failures; with the combined operation 62 per cent of successes and no complete failures; and with the complete Lane operation 33 per cent of successes and a good many failures In performing the Langenbeck operation he made use of a very long incision on either side, dividing the anterior pillar of the fauces, after which the two surfaces of the palate were sutured in the middle line with very fine fishing gut The one thing he feared was tension

Mr KELSEY FRY, speaking as a dental surgeon, said that if surgeons would provide for the cleft-palate patient a functional soft palate it would be an easy matter for the dentist to provide a hard palate

Mr F W. GOYDER (Bradford) said he operated fairly late, rarely on patients under 3 years, following Langenbeck's method except when the clefts were very wide. In his last 22 cases he had used a flap in 11 and the median operation in the other 11. Even when doing the Langenbeck operation he used narrow flaps and united them so as to leave no raw surface

Mr L E BARRINGTON-WARD said he had operated on 148 patients, with six failures One of these was a horseshoe cleft, which was usually the most difficult, three had deficiencies in hard or soft palate, and in two the alveolus was still cleft Recent speech-testing in 58 of these patients gave 20 good results, 18 fair, and 20 bad, among the bad were four mentally deficient If a hare-lip was associated with the deformity the operation should take place as early as possible; his usual rule was to do it at 1 month. The palate itself he preferred to do at 18 months or 2 years, or even later. He did Langenbeck's (which he thought posterity would call Berry's) operation, lateral approximation to median suture, using the finest ophthalmic silkworm-gut He believed that relaxation sutures nearly always cut out or produced ulceration With regard to prognosis in the matter of speech he would be guided not so much by the type of cleft as by the intelligence of the mother

Mr TWISTINGTON HIGGINS said he had operated on 47 cases since 1921, using the modification of Gillies—a relatively easy procedure—the only difficulty being the epithelial graft with which it was necessary to cover the raw area He had also adopted Mr. Addison's technique in 15 cases, removing the tonsils previous to operation, for they were often infected without external sign to show it

The PRESIDENT, in summing up the discussion, said that he had been struck by the extraordinarily hopeful outlook there was now for the child born with cleft-palate He was sorry that not more had been heard about the Brophy operation.

Sir JAMES BERRY and Mr. GREY TURNER briefly replied.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society took place on May 27th, Sir HUMPHRY ROLLESTON, the President, in the chair

Dr. GEORGE RIDDOCH read a paper on the

PROGNOSIS AND TREATMENT OF NEUROSYPHILIS

The localisation of the virus to the nervous system, he said, was never more than relative; the functions of the other organs might be deranged, or those of the body as a whole might be impaired by the spirochæte The defensive reaction of the patient to the invading parasite must be considered, and differences in the severity of tabes in different people were not due merely to differences in the strength of the virus

Two important questions arose (1) Could the disease be arrested? (2) If so, how much disability would be left? Probably there was no natural immunity to the disease, but the history of syphilis showed that considerable inherited resistance was present. In estimating the prognosis in any particular case the patient's power to combat the infection was very important It would be influenced, moreover, by such non-specific factors as nephritis, diabetes, urinary sepsis secondary to paralysis of the bladder, or by faulty habits such as abuse of alcohol. Another important point was the duration of the disease and of its nervous manifestations. Early diagnosis was very necessary, for obviously a patient whose tabes was detected when there were but few physical signs was a better subject than one who already had multiple and extensive lesions in the nervous system The same held true in cerebral syphilis.

Meningovascular syphilis was more amenable to treatment than the parenchymatous forms, because it was difficult for drugs circulating in the blood stream to reach organisms in nerve tissue When definite mental symptoms, such as dementia and delusions, occurred in cerebral syphilis it was evident that encephalitis was present, and the state of affairs was very difficult to deal with, there was less chance of making the patient a "good life" than if the disease had been caught earlier. Epilepsy as a sequel of cerebral syphilis indicated encephalitis of a serious kind. Optic neuritis had a similar significance, but cranial nerve palsies might be due to involvement of a nerve in its extracranial course, rather than to an active arterial lesion, and this did not imply so serious an outlook In spinal syphilis there was, of course, a better chance of eradicating the disease if the infection had not caused severe paraplegia with its probable disturbance of the bladder. It was always necessary to bear in mind the tendency of neurosyphilis to undergo remission and relapse, even after treatment had made the laboratory tests negative It might be said that with efficient treatment tabes could be arrested in half the cases, but this did not by any means imply that treatment should be discontinued after the arrest Tabes was now seen earlier at neurological clinics, and it was rare to see patients who on their first application were grossly ataxic or nearly blind For this improved state of affairs he thought the general practitioner was largely responsible

General paralysis of the insane, continued Dr. Riddoch, was a much more discouraging condition, and before malarial treatment was instituted the outlook had been almost desperate, death being rarely deferred for more than two or three years Malaria gave ground for hope, though its value could not yet be assessed

There was a group of cases of what could be described as occult neurosyphilis There was a danger of confusing this condition with ordinary neurasthenia, because it was accompanied by lassitude, defective concentration, and emotional instability; or it might be wrongly attributed to alcoholic indulgence Probably the symptoms were mostly due to a mild meningoencephalitis rather than to gross

Lateral approximation, said Sir James Berry, was the method most surgeons now employed, though there was a good deal of difference of opinion concerning it. His own impressions were based upon an experience of 33 years, during which time he had operated on 276 cleft-palates. A precedent to the operation should be the removal of gross defects of teeth and tonsils, not necessarily a routine excision of tonsils and adenoids. Nor was it needful to attempt asepsis of the mouth some days before operating. The general health of the child must be good and nasal catarrh must first be cured. The posture he preferred to adopt when doing these operations was to stand on the right side of the patient facing the head, which was thrown well back with shoulders raised, so that the blood ran into the upper part of the pharynx, not into the larynx. The disadvantage of this posture was occasional faintness, but the bleeding was less than in any other posture. Smith's gag was to be preferred if the assistant had been trained in the holding of it.

On two points, Sir James Berry said, he would like to hear the opinion of others. The first was the extent to which the soft tissues should be separated from the bony palate. Unless the separation were thorough the soft palate, even if that alone were affected, could not be brought down sufficiently for the pared edges to be pulled together without tension, and tension meant failure of union. The separation was best brought about, in his opinion, from inside the cleft, avoiding the vicinity of the posterior palatine artery. The nasal intonation characteristic of cleft-palate speech was caused by abnormal air entry into the nose, which in normal people was avoided by raising the soft palate and by lateral approximation of the palato-pharyngeal muscles. The second point was the need of making lateral incisions to relieve tension. With wide and difficult clefts such incisions were frequently essential, on one side or both, but seldom should they exceed half an inch in length, unless for secondary operations for large holes in the hard palate. Of recent years his practice had been to employ these incisions less and less, replacing them by deep-tension stitches and rubber plates, after the manner of Brophy. Stout fishing gut tended to cut out, he had tried putting short pieces of rubber tubing on the suture, but they buckled and caused ulceration. Eventually he had found satisfaction in flat oval discs of sheet rubber threaded on stout fishing gut. They did not increase the liability to sepsis if removed on the fifth day, by which time union should be strong enough to stand the strain imposed by the palatine muscles. They would be useless for the thinner tissues of the hard palate. He had had no experience of the very long lateral incisions; he thought they must damage unduly the palatine and pharyngeal muscles.

The less after-treatment the better the result. For at least a week the diet must be confined to milk or milk and water, no washing, wiping, or spraying of the mouth was allowed, apart from a drink of warm water after each feed. The child should be kept in the fresh air as far as possible. He did not examine the palate until four days after the operation, and decided then how soon the plates should be removed.

Mr. Grey Turner spoke from an experience of 155 cases of cleft-palate, upon whom 195 operations had been done with four deaths. The average age at operation of the children under 12 was 4 4/12 years, and of those over 12 was 18 9/12 years. The oldest was 40. He had been able to examine 79 of these cases 1–24 years after operation and to estimate the functional result in 90. These he classed as: very good or normal, 10; good, 35; fair or moderate, 25, bad or poor, 17; unintelligible, 3. In 11 cases operations had previously been performed by other surgeons. Failure of union occurred only once. In 44 cases in which the palate was completely restored anatomically speech was normal in 7 cases, good in 20, fair in 14, bad in 3. In 12 the operation was still too recent to assess the result. To ensure success from the speech standpoint the patient should be left with a good soft palate, and if possible one which was sensitive. The varying result was, he thought, connected with the architecture of the nasopharynx and with the neuromuscular apparatus. Integrity of the sphincter just behind the soft palate had much to do with perfect speech. He did not hesitate himself to operate on soft palates within the first year of life and to allow the infant to return home. A lateral incision, though often necessary, was not an essential part of the operation. Tension must be avoided at any cost. Suture material should be of a sort which did not absorb the secretions of the mouth, he now used chromicised catgut. In certain cases much could be accomplished by a secondary operation, he had operated four times on one patient. He would like to know how holes in the palate could be avoided. In regard to hare-lip, he had found that large anterior nares facilitated the escape of air through the nose, and might interfere with a good functional result.

Discussion.

Mr. O. L. Addison condemned the flap operation. He did not think there was any advantage in operating before the age of learning to talk; the older the patient when operated upon the more likely were anatomically good results to ensue. He preferred the long lateral incision to avoid tension. Before touching the palate he always removed the tonsils, which he regarded as a source of potential sepsis. All his patients were Dick tested beforehand, and if positive received a dose of serum. Of his 77 cases two died, one from reactionary hæmorrhage the night following operation, the other from convulsions under the anæsthetic.

Dr. Victor Veau (Paris) said he had operated upon 89 children's palates by the Langenbeck method, and in 74 there was total closure, in 13 imperfect closure, in 3 the operation was a total failure, 25 per cent. of the patients spoke well after the operation. He described his present procedure, which consisted in turning up a flap from the vomer and carefully suturing the mucous membrane, thus preventing scar formation. He showed some phonographic records.

Mr. A. T. Pitts dealt with the subject from the point of view of the dental surgeon. Surgical treatment, he agreed, was better than condemning the patient to wear a prosthetic appliance, but when surgical efforts had been given a trial and failed the patient's condition was always worse and serious deformities of the jaw might follow. Cases of this kind needed the closest cooperation between surgeon and dentist.

Mr. Cyril Nitch gave records of 86 cases (with four deaths) of which only 43 could be traced to discover speech results. The age at which the cleft should be closed depended, he thought, on the type of operation done. The flap operation of Lane should be performed about four months before the teeth were developed. He had not, however, performed that operation since 1913, for though the cleft could be closed with certainty, the soft palate was always short and rigid, and the speech correspondingly bad. The age he generally selected for operation was from 18 months to 2 years. He always tried to close the whole cleft at one operation, provided the anterior palatine arch could be preserved. He made long lateral incisions at the posterior border close to the alveolus, curving outwards and downwards towards the last lower molar tooth. The mother should be taught to massage the soft palate after operation. Since he had adopted Langenbeck's operation with long tension-relieving incisions and lateral splints his failures had been reduced to 17 per cent., as compared with 50 per cent. with the unmodified Langenbeck.

Mr. Cortlandt MacMahon spoke of the speech-training of these patients. The difficulty was with the letters *k*, *g*, *d*, and *t*, but especially the letter *s*. The letter *s* could be restored in the speech of these patients by driving the tongue down so as to produce tension between the soft palate and the back of the tongue. He believed that under training the Lane operation would give good speech, but if the training was deficient the Langenbeck method gave the better result.

Mr. H. D. GILLIES made some remarks on secondary operations. The great majority of cases, he said, would be vastly improved by severing the soft from the hard palate, making provision for an epithelial covering of all raw areas, interposing an appliance between the soft and the hard palate, and allowing the soft palate to assist in shutting off the nasal from the buccal cavity.

Mr. C. H. FAGGE said that up to the end of 1924 he had operated 218 times on 114 cleft-palate patients, some of these operations were on the lips, others for closure of holes in the palate. On the largest group of cases, those of complete unilateral cleft, he first performed a Lane's flap operation on the hard palate, then a hare-lip operation, and finally closed the soft palate at a second sitting. He had never failed to close a hard palate with a Lane's flap, nor had he seen one break down. Lane's operation did not make the operation on the soft palate any more difficult. He had an impression that whenever he could close both the hard palate and the soft before the first dentition commenced he would obtain a good anatomical result. With the Langenbeck operation pure and simple he had had about 60 per cent. of successes and 5 per cent. of complete failures, with the combined operation 62 per cent. of successes and no complete failures; and with the complete Lane operation 33 per cent. of successes and a good many failures. In performing the Langenbeck operation he made use of a very long incision on either side, dividing the anterior pillar of the fauces, after which the two surfaces of the palate were sutured in the middle line with very fine fishing gut. The one thing he feared was tension.

Mr. KELSEY FRY, speaking as a dental surgeon, said that if surgeons would provide for the cleft-palate patient a functional soft palate it would be an easy matter for the dentist to provide a hard palate.

Mr. F. W. GOYDER (Bradford) said he operated fairly late, rarely on patients under 3 years, following Langenbeck's method except when the clefts were very wide. In his last 22 cases he had used a flap in 11 and the median operation in the other 11. Even when doing the Langenbeck operation he used narrow flaps and united them so as to leave no raw surface.

Mr. L. E. BARRINGTON-WARD said he had operated on 148 patients, with six failures. One of these was a horseshoe cleft, which was usually the most difficult, three had deficiencies in hard or soft palate, and in two the alveolus was still cleft. Recent speech-testing in 58 of these patients gave 20 good results, 18 fair, and 20 bad, among the bad were four mentally deficient. If a hare-lip was associated with the deformity the operation should take place as early as possible; his usual rule was to do it at 1 month. The palate itself he preferred to do at 18 months or 2 years, or even later. He did Langenbeck's (which he thought posterity would call Berry's) operation, lateral approximation to median suture, using the finest ophthalmic silkworm-gut. He believed that relaxation sutures nearly always cut out or produced ulceration. With regard to prognosis in the matter of speech he would be guided not so much by the type of cleft as by the intelligence of the mother.

Mr. TWISTINGTON HIGGINS said he had operated on 47 cases since 1921, using the modification of Gillies—a relatively easy procedure—the only difficulty being the epithelial graft with which it was necessary to cover the raw area. He had also adopted Mr. Addison's technique in 15 cases, removing the tonsils previous to operation, for they were often infected without external sign to show it.

The PRESIDENT, in summing up the discussion, said that he had been struck by the extraordinarily hopeful outlook there was now for the child born with cleft-palate. He was sorry that not more had been heard about the Brophy operation.

Sir JAMES BERRY and Mr. GREY TURNER briefly replied.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society took place on May 27th, Sir HUMPHRY ROLLESTON, the President, in the chair. Dr. GEORGE RIDDOCH read a paper on the

PROGNOSIS AND TREATMENT OF NEUROSYPHILIS

The localisation of the virus to the nervous system, he said, was never more than relative, the functions of the other organs might be deranged, or those of the body as a whole might be impaired by the spirochæte. The defensive reaction of the patient to the invading parasite must be considered, and differences in the severity of tabes in different people were not due merely to differences in the strength of the virus.

Two important questions arose: (1) Could the disease be arrested? (2) If so, how much disability would be left? Probably there was no natural immunity to the disease, but the history of syphilis showed that considerable inherited resistance was present. In estimating the prognosis in any particular case the patient's power to combat the infection was very important. It would be influenced, moreover, by such non-specific factors as nephritis, diabetes, urinary sepsis secondary to paralysis of the bladder, or by faulty habits such as abuse of alcohol. Another important point was the duration of the disease and of its nervous manifestations. Early diagnosis was very necessary, for obviously a patient whose tabes was detected when there were but few physical signs was a better subject than one who already had multiple and extensive lesions in the nervous system. The same held true in cerebral syphilis.

Meningovascular syphilis was more amenable to treatment than the parenchymatous forms, because it was difficult for drugs circulating in the blood stream to reach organisms in nerve tissue. When definite mental symptoms, such as dementia and delusions, occurred in cerebral syphilis it was evident that encephalitis was present, and the state of affairs was very difficult to deal with; there was less chance of making the patient a "good life" than if the disease had been caught earlier. Epilepsy as a sequel of cerebral syphilis indicated encephalitis of a serious kind. Optic neuritis had a similar significance, but cranial nerve palsies might be due to involvement of a nerve in its extracranial course, rather than to an active arterial lesion, and this did not imply so serious an outlook. In spinal syphilis there was, of course, a better chance of eradicating the disease if the infection had not caused severe paraplegia with its probable disturbance of the bladder. It was always necessary to bear in mind the tendency of neurosyphilis to undergo remission and relapse, even after treatment had made the laboratory tests negative. It might be said that with efficient treatment tabes could be arrested in half the cases, but this did not by any means imply that treatment should be discontinued after the arrest. Tabes was now seen earlier at neurological clinics, and it was rare to see patients who on their first application were grossly ataxic or nearly blind. For this improved state of affairs he thought the general practitioner was largely responsible.

General paralysis of the insane, continued Dr. Riddoch, was a much more discouraging condition, and before malarial treatment was instituted the outlook had been almost desperate, death being rarely deferred for more than two or three years. Malaria gave ground for hope, though its value could not yet be assessed.

There was a group of cases of what could be described as occult neurosyphilis. There was a danger of confusing this condition with ordinary neurasthenia, because it was accompanied by lassitude, defective concentration, and emotional instability; or it might be wrongly attributed to alcoholic indulgence. Probably the symptoms were mostly due to a mild meningoencephalitis rather than to gross parenchymatous changes Even the pathologist could not always determine whether a patient had syphilitic neurasthenia or early general paralysis of the insane, as the blood might be Wassermann-positive, while the cerebro-spinal fluid was unchanged. It was unwise to lay too much stress on laboratory tests and they must be related to the patient's general state It would be a great mistake to assume that a negative Wassermann reaction following a positive one meant that the patient had got rid of his infection, for it might again become positive, either with or without treatment It was important to know how a patient had dealt with his early infection, as this helped to indicate the degree to which he would combat the later manifestations If early treatment had been thorough the later development was of more serious significance A patient should be told that he might become worse before the treatment had its full effect

Treatment

The general principle to be kept in mind in treatment, said Dr Riddoch was that antisyphilitic remedies were only an aid to the natural resistance of the body ; if used injudiciously they were poisonous to the tissues How could the natural resistance be kept at its highest level ? A quiet, healthy life was necessary, with adequate rest and attention to diet In the tabetic the relief of pain was of considerable importance Amongst things forbidden should be excessive indulgence in tobacco and alcohol and excessive sexual intercourse, whilst in women pregnancy should be discouraged It was important to maintain the morale of these patients so that they would persist with treatment Massage and exercises might be needed Séquard advised daily small doses of salvarsan, either subcutaneously or intravenously, up to 60 injections, without mercury or iodide of potassium In most cases under this treatment the ankle-jerks disappeared after six to ten injections, and Dr Riddoch looked upon this as an indication of active poisoning of peripheral nerves due to administration of the drug being unduly pushed Some advised a preliminary course of mercury before using arsenical preparations, and he believed that salvarsan used alone was less effective than when combined with mercury or bismuth, iodide of potassium being given in all forms of neurosyphilis except general paralysis of the insane He had not found that silver salvarsan gave better results than novarsenobenzol, with potassium iodide by the mouth Tryparsamide had been reported on favourably from the Rockefeller Institute, but he did not think it could yet be said whether it was better than the ordinary arsenical preparations, of which novarsenobillon was the one most used in this country, its capacity being well known and its toxicity controlled He could not say much in favour of salvarsanised serum ; indeed, he had seen aggravation of root-lesions follow its use He did not think any patient should be treated continuously simply because his Wassermann was positive

To be suitable for malarial treatment a case of general paralysis of the insane should be taken early and should be free from cardiovascular and renal disease A patient whose brain had been partially destroyed, with consequent dementia, might recover sufficiently to enable him to do work which did not exact much from him Whilst infected by malaria the patient might exhibit an acute psychosis, or even become maniacal, but he would probably reach his previous mental state on recovering from the malaria

After vascular and parenchymatous lesions, said Dr Riddoch in conclusion, some permanent damage always followed The main indication of the efficacy or otherwise of treatment must be the clinical findings, though help was obtainable from laboratory tests It was very important not to push antisyphilitic remedies unduly, and it was necessary to keep careful watch for signs that the limit of the patient's tolerance had been reached.

Discussion

The PRESIDENT spoke of the possible relationship which amyotrophic lateral sclerosis and disseminated sclerosis might bear to syphilis He asked whether it was the general view that syphilitic hemiplegia due to arterial disease was now rarer than formerly. Was the diminishing frequency of tabes due to earlier and more thorough treatment of syphilis, or was it likely to be due to some special organotropic strain of the spirochæte ? He was reminded of cases described by Erb in which patients given vigorous mercurial treatment had developed what appeared to be tabes, but was in reality polyneuritis There was no doubt that tabes and general paralysis were never cured Referring to the treatment of general paralysis by malaria, he mentioned some fatal cases in Dublin in which the patients had been given the malignant tertian infection With benign tertian malaria there seemed little risk of harm

Colonel L W. HARRISON did not agree with Dr Riddoch's criticism of silver salvarsan ; he thought it caused more improvement than any other arsenical preparation He preferred to use it by the deep subcutaneous method After a patient with general paralysis had been treated with malaria, the cerebro-spinal fluid should not be examined until three months after the malarial paroxysms had ceased His view was that bismuth was a much more valuable drug in the treatment of neurosyphilis than mercury, especially when it was given together with large doses of potassium iodide

Dr C P SYMONDS remarked that the difficulty in assessing the value of any treatment of neurosyphilis lay in the fact that most people had comparatively little experience of the course of the untreated disease From observing cases which had not come for treatment until a late stage he concluded that, apart from syphilitic encephalitis, neurosyphilis was a self-limited disease He had found novarsenobenzol more valuable than mercury in neurosyphilis, and it was important to push remedies to the patient's point of toleration Even if some cases showed jaundice the price was justified in the amelioration of the syphilis In meningeal forms iodide was a very valuable drug He agreed with Dr Riddoch that treatment should be determined by the clinical condition rather than by the serological reactions There seemed no doubt that in a proportion of cases the life of a general paralytic would be prolonged by several years by inducing an attack of malaria In parenchymatous neurosyphilis it was hard to give a prognosis, in tabes he did not think it was safe to promise anything

Dr H M. HANSCHELL related the course of events in 12 cases of general paralysis of the insane which he had treated with malaria In three cases of tabes similarly treated the Wassermann reaction was negative in the cerebro-spinal fluid three months after the malaria was cured

Mr WANSEY BAYLY described a case in which a dramatic apparent cure of general paralysis followed a course of malaria

Dr W. D. NICOL spoke of experience of the treatment at Horton Mental Hospital Many patients with general paralysis of the insane had improved greatly The paranoid patients reacted worst

Dr S C WOODHOUSE spoke of the blood and cerebro-spinal fluid picture in cases of tabes, and Dr J. G GREENFIELD referred to the inflammatory reaction in the brain after malarial treatment

Dr SHARPE and Mr C H MILLS also joined in the discussion

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this Society held on May 4th Dr A NINIAN BRUCE read a paper on the

Treatment of Locomotor Ataxia

with special reference to the ataxia Locomotor ataxia or tabes dorsalis was, he said first clearly defined as a separate clinical entity by Duchenne, of Boulogne, in 1841–51, and much speculation and controversy took place before it was established that it was due to a syphilitic infection of the nervous system. It is now known that the lesion affects the posterior sensory nerve-roots, and that the optic nerve is also liable to be involved. As the spirochæte limits its attack so largely to the sensory fibres, the resulting symptoms tend to be purely sensory, and it is thus important to realise that apart from impulses of pain, touch, heat, and cold which pass centralwards by this pathway and reach consciousness, a very large group of sensory impulses also utilise this pathway but remain at the physiological level, and thus do not enter consciousness; they are concerned with the maintenance of posture and equilibrium and such fibres arise from the tendons, muscles, and joints.

Apart from blindness, said Dr. Bruce, ataxia is the most serious symptom from which a tabetic may suffer as it deprives him of his power of locomotion; it is also a symptom which tends to progress and ultimately leaves the patient in a bed-ridden state. In fact, tabes is often divided into three stages (1) the pre-ataxic, (2) the ataxic, and (3) the paralytic, depending entirely upon the progress of the ataxia. It is interesting to note that many observers have drawn attention to the fact that a tabetic who is blind is not ataxic, and that the development of blindness in an ataxic man usually results in the disappearance of his ataxia. Tabes is not a lethal disease and does not necessarily affect the average duration of life to any great extent. Involvement of the posterior sensory root in tabes results in an interference with postural information passing centralwards and thus leads to a disturbance of reflex action. This delay and diminution of postural stimuli creates confusion in the pathways of nervous integration and the information reaching the end-stations is misleading. Endeavour is then made to counteract the errors by vision, and information of posture is obtained through the visual pathway. This, however, is a much more complicated mechanism than the one based on purely postural images which has been thrown out of gear. The replacement of a physiological mechanism by a more complicated one involving consciousness is inefficient and leads to fatigue. At the same time the misleading postural images are repressed and the new visual mechanism, becoming more and more complex and fatigued, leads to muscular incoordination and ataxia. This inexplicable symptom rapidly progresses; the more the ataxic tries to walk, the worse he becomes. Mental demoralisation and chaos set in, he surrenders to what he regards as the inevitable, and is usually stated now to have reached the paralytic stage. Walking was originally learned from visual images, and it is only later when postural images are established that visual images are discarded. A good pianist keeps his eyes fixed on the music, the fingers wandering up and down the keyboard controlled only by postural images.

The treatment of ataxia, went on Dr. Bruce, consists in relearning the use of postural images; visual images may require to be cut out by blindfolding the patient. That postural images may be cultivated to a high degree is shown by acrobats and tightrope walkers. They are best relearned by first creeping until this can be done with ease, and then kneeling and walking on the knees. When this is learned it may be followed by standing supported and unsupported, by various muscular movements and exercises, and finally by walking, by going up and down stairs, and by all the other muscular movements required in daily life. The mental relief obtained is enormous. A pre-ataxic case, properly handled, need never become ataxic. To a large extent, therefore, the proper treatment of tabes really closely resembles that of syphilitic neurasthenia, and the disease itself may be more correctly regarded as syphilitic neuritis of the posterior roots. The condition illustrates well the fact that organic disease may produce functional nervous symptoms, which, when once developed, may steadily progress, although the organic lesion itself may remain more or less stationary.

Reviews and Notices of Books.

MODERN MEDICINE:

Its Theory and Practice. In Original Contributions by American and Foreign Authors. Edited by Sir WILLIAM OSLER. Third edition. Thoroughly revised and re-edited by THOMAS MCCRAE, M.D., assisted by ELMER H. FUNK, M.D. Vol. IV., *Diseases of the Respiratory System; Diseases of the Circulatory System.* London: Henry Kimpton. 1927. Pp. 1011. In sets of six volumes only. £12 12s.

THE publication of a third edition of this well-known system of medicine is a sign of its established reputation. It is a sign, too, of the rapidly changing times which make even works of reference quickly out of date. This fourth volume on diseases of the respiratory and circulatory systems covers a thousand pages, and does not include chapters on lobar pneumonia and pulmonary tuberculosis, which very properly are treated in another volume. A standard work of medicine, the authors of which must plod solidly through the systems, can hardly be expected to attain to the same level of excellence throughout. This volume is no exception. The section on bronchiectasis, for example, is disappointing, even when allowance is made for the obstinacy of this particular task. The bacteriological aspect of bronchiectasis and the clinical classification are dealt with too briefly, whilst the value of the radiogram, of lipiodol, and of the newer surgical operations receives no special mention. At the beginning of the section on respiratory diseases there is a useful summary of the physiology of respiration which serves as a good introduction to the first part of the book. The phenomena of cyanosis are not all specified here, though the admirable work of Lunsgaard and Van Slyke on this subject is adequately discussed under congenital cardiac disease. In a subsequent edition a short section on the clinical examination of the normal chest in the light of what modern radiography has taught us might well be inserted. The chapter on the phenomenon of hypersensitiveness including protein sensitisation, hay-fever, and asthma, is a good exposition of a subject which must have been difficult to condense into 30 odd pages.

The second part of the book on diseases of the circulatory system contains two quite brilliant chapters. The first of these is on the rate and mechanism of the heart-beat by Sir Thomas Lewis, and the other on congenital cardiac disease by Dr. Maude E. Abbott. The former is a full and lucid account of a subject which gives much anxiety to the practitioner. It is not overburdened with the technicalities of the electrocardiograph or with baffling formulæ and diagrams, but is clearly and simply written. It contains, furthermore, a helpful summary of the new work on quinidine. The chapter on congenital cardiac disease occupies one-fifth of the whole book and is not a page too long. It is indeed a really excellent monograph on the subject, one which goes far to make Vol. IV. of this system of medicine a standard work. A general survey of the plan of the volume leads one to the conclusion that the pathology in most sections is condensed into almost too small a space, notably in matters bacteriological. Treatment, moreover, looms none too large, and this is dangerous in so far as the student is only too ready to believe that diagnosis is the end and aim of the physician. This last criticism might be applied to many modern text-books of medicine—a sign of a transition period which marks the passing of the art of symptomatic healing and the birth of the science of accurate differential diagnosis with its accessory instruments and laboratories. The borderline where treatment becomes surgical especially deserves fuller discussion than is here given. Nowadays the physician must be sufficiently conversant with surgical procedure and practice to cooperate intelligently with the surgeon.

In general this fourth volume can be confidently recommended as a good summary of modern medicine in the particular subjects with which it deals, and we look forward to the completion of a work on which many students and practitioners have learnt to rely. A last word may be a plea for a stronger binding for a reference book which will so often be taken from the shelf.

MANUAL OF MEDICINE.

Third edition. By A. S. WOODWARK, C.M.G., O.B.E., M.D., F.R.C.P., Physician, Lecturer on Medicine, and Dean of the Medical School, Westminster Hospital. London: Humphrey Milford, Oxford University Press. 1927. Pp. 513. 15s.

SINCE the second edition of this well-known manual was published in 1920 various advances in medicine have necessitated alterations and additions to the text; but the size of the book remains substantially the same and it can still claim to be a "manual." In the section on the liver van den Bergh's test is described, but catarrhal jaundice is still left under the misleading heading of "gross obstruction of the common bile-duct." Cholecystography is mentioned in the diagnosis of gall-stones, according to many observers, the oral method is not so unsatisfactory as is here implied. The use of lipiodol in the diagnosis of bronchiectasis is described, and insulin treatment is well discussed in the section on diabetes. A good account of the pathogenesis of asthma is given, without undue emphasis upon protein hypersensitiveness. Some portions of the section on the heart are disappointing; no mention is made of "circus movement" in the pathology of auricular flutter and fibrillation, and quinidine is too valuable and interesting a drug to be dismissed as "gr. v, t.d.s." Apart from these small points the book shows signs of careful revision, and remains an excellent guide to medicine.

SURGERY.

Manual of Operative Surgery. Sixth edition. By Sir HOLBURT WARING, M.S., B.Sc., F.R.C.S., Surgeon to St. Bartholomew's Hospital; Examiner in Surgery, University of Oxford. London: Humphrey Milford, Oxford University Press. 1927. Pp. 868. 18s.

Sir Holburt Waring has thoroughly revised this latest edition of his work. Its good reputation should be further enhanced by improvements and additions, and by the deletion of accounts of obsolete methods. It is a really good practical text-book of operative surgery; the author has made it more than a compilation by drawing upon his long experience to advise on the choice of operation and to comment on the results he has found to follow the different procedures. We see how his process of selection has taken place, for instance, in the section upon cleft-palate, where all reference to the Davies-Colley operation has been omitted, a decision with which most surgeons will agree. On the other hand, implantation of the ureters into the rectum in ectopia vesicæ can give brilliant results and is worth consideration in a book of this kind. It is interesting to note that the author favours a somewhat lateral intracranial approach to the pituitary body.

The diagrams illustrating lymphatic drainage and the principles upon which malignant surgery of the different organs should be carried out are particularly helpful in this edition. There is also a useful description of general surgical technique and theatre appliances, to which the author has devoted considerable attention.

Surgical Applied Anatomy. Eighth edition. By Sir FREDERICK TREVES. Revised by C. C. CHOYCE, B.Sc., M.D. Edin., M.B., F.R.C.S., Professor of Surgery in the University of London, Surgeon to University College Hospital. London: Cassell and Co., Ltd. 1926. Pp. 727. 14s.

THIS classical manual on surgical anatomy has been thoroughly revised and brought up to date by Prof. C. C. Choyce. It has been deservedly popular in the past, and is likely to become more so in the future. It will be particularly acceptable to the senior student, since it combines the outlook of an anatomist and the views of a surgeon. It is complete and exact in its statements, full of really useful diagrams, easy to read, and contains the kind of information which is often very difficult to find. The book is, perhaps, a little long for the ordinary student to read right through, but it is not easy to see how any portions or even paragraphs could have been omitted. It is one of the best treatises on surgical anatomy available to English students.

FOOD VALUES.

For Calculating Diabetic and Nephritic Diets. Calculated from Bulletin No. 28, U.S.A. Department of Agriculture. By LOUISE M. KEEGAN, University of Chicago Dietitian, Polyclinic Hospital, New York City. New York: The Macmillan Company. 1926. Pp. 106. 7s.

Food Values and Recipes for Diabetics. Second edition. By S. MILLER, M.D., and F. B. SMITH, M.D. Belfast: R. R. Browne and Co. 1926. Pp. 23. 2s. 6d.

THE composition of foods, though such an important branch of medical science, is little studied in this country in comparison with Canada and the United States of America. The most complete publication on the subject is Bulletin No. 28 of the U.S.A. Department of Agriculture, for which Attwater and Briant are responsible; practically all the books of food values which have been published are based on their figures. The information in the Bulletin is so voluminous that it is necessary to issue some sort of abridged version—for example, that no less than 57 portions of beef are analysed is quite sufficient to confuse the ordinary person, especially as he is unlikely to be able to identify the joints referred to. Miss Keegan has considerately reduced the portions of beef to 20. The protein content of these varies from 14 to 24 g. per 100 g. of meat (average value 18 g.). The fat varies from 3 to 28 g. per 100 g. (average 16 g.). Even for the abridged tables considerable knowledge of the different joints of meat is required. If it is necessary to record the exact amount of protein and fat in the diet, very accurate tables of this type are essential. In most of the big hospitals in Canada and U.S.A. a special kitchen is established with one or more skilled dietitians in charge; it is thus possible to ensure the control within narrow limits of the number of grammes of protein, fat, and carbohydrate consumed by any patient. Miss Keegan's tables are well adapted to serve this end; it is possible with their help to give to patients in hospital much variety without altering the essential composition of their diet by more than a few grammes. Whether the patients who have left hospital will even after careful training have the ability or indeed the knowledge or the time to worry over the difference between a sirloin of beef and a porter-house steak is another matter.

The tables prepared by Dr. Miller and Dr. Smith are suitable for a very different type of patient. Thus in one table the food values of beef, lamb, mutton, pork, and veal are all classed as identical, though in the full tables three kinds of beef are given, one of lamb, two of mutton—all varying slightly from the group figure. For the skilled dietitian these tables are valueless, but for the average diabetic patient in England they should suffice, though it would be of assistance if the caloric values were also given. Incidentally nearly all the English tables omit this information, which is supplied in American tables as a routine. Dr. Miller and Dr. Smith have given all their food values in terms of 1 oz. This form of notation is convenient, but does not make substitutions so easy as the alternative scheme, first put forward by Dr. O. Leyton, of giving the weights of the different foods which contain 5 g. of carbohydrate. It is, for example, easy to substitute raspberries for grapes without doing any of those calculations which many patients are incapable of grasping. In a future edition this notation should be adopted by Dr. Miller and Dr Smith, since the intelligence of patients varies greatly, and many elderly women are incapable of doing even division sums without much trouble In other respects patients will find the tables easy to follow, while the recipes given will be most useful to those whose diets have to be strictly controlled

To those who are sceptical of the need for such detailed instructions we would point out that in the future even the most hardy among us may be encouraged to choose his meals on this plan; in certain restaurants in New York already the caloric values of the different dishes on the menu are set out so that the hungry man can know which gives the best food value.

THE SHIP-SURGEON'S HANDBOOK

Third edition By A VAVASOUR ELDER, D S C, M R C S, L R C.P, Surgeon Lieut-Commander, R N V.R London · Baillière, Tindall and Cox 1927 Pp 523 10s. 6d.

THIS book will prove of great value to doctors going to sea for the first time in medical charge; it will keep them out of many difficulties, professional and social They will find it easier to use a microscope on board than the author allows, indeed, a microscope must be carried on some foreign liners for the diagnosis of malaria, plague, and typhoid fever Much helpful detail is given for managing a case of sea-sickness, though the treatment advocated in the closing summary is frankly expectant Good advice will be found here for practitioners who wish to send their patients for voyages, due regard being paid to the diseases from which these are suffering or recovering, and to the voyages appropriate to each season. The author holds that doubtful cases of pulmonary tubercle may be sent on short voyages, that early cases do better in sanatoriums and that there is no place for advanced cases on board ships owing to the great risk of hæmoptysis The chief anxiety of ship-surgeons at the moment seems to centre round the immigration officer, who is only to be disarmed by frankness and accurate papers The author has good words to say even for Ellis Island, and suggests that the minute examination of British seamen at New York, of which so much was heard a year ago, was initiated because so many seamen were deserting and so many fraudulent and unfit immigrants were being clandestinely received into the United States A striking paragraph (p 411) describes anew the old seafaring disease, of which we have heard no mention for years, called calenture The sufferer from calenture has the temporary delusion that the sea is a green field, full of flowers so clearly seen that the patient may even go overboard to pick them

INTERNATIONALE RADIOTHERAPIE

By Dr. J WETTERER Darmstadt. L C Wittich 1925–26 Band I. Pp 1056

THE author has set himself the task of bringing into a single volume abstracts of the international literature on radiotherapy for 1925–26, and further volumes are projected if his labours meet with an adequate response Those who are in touch with the present position of radiological treatment and its developments are aware of the need for such a book, the subject being one which can hardly be covered at the present moment by any text-book

Dr. Wetterer's abstracts have been fully and conscientiously made The details of technique and statistics of results have been carefully given without undue condensation, and his work is thus most valuable for reference Dr Wetterer deserves praise for the enthusiasm which has enabled him to carry out so vast a task. We would suggest in future editions the index of authors should include their initials It may be hoped that English radiologists will coöperate to the utmost with Dr. Wetterer in supplying him with published material, as he is endeavouring to make the volume in the fullest sense international

A TEXT-BOOK OF EMBRYOLOGY.

By H E JORDAN and J E KINDRED, of the University of Virginia London and New York: D. Appleton and Co 1926 Pp 613 25s.

THIS book differs from the ordinary students' book on the subject in scope and detail Among its best features are the chapters and sections given to general considerations, such as sex-determination and recapitulation These are well and clearly put, and give a fair and just conception of the points at issue The majority of the illustrations are good, but some are crude and of little value as exponents of the text. The histological details of structure and formation are a prominent and good feature The treatment of the general subject matter of the book itself does not rise in any way above the ordinary level; on some points the authors are not in agreement with what is usually taught in this country to-day. More attention might, with advantage, have been paid to correction of proofs and verification of references; in this connexion we may point out that Prof Thomson's papers on the ovum appeared in the (English) *Journal of Anatomy* in 1919

The book is clearly printed and well produced, and has at its end a chapter on laboratory work, in which are some excellent figures of sections of embryonic stages in certain lower animals.

MONOGRAPH ON BIOCHEMISTRY.

Lecithin and Allied Substances: the Lipins. Second edition. By HUGH MACLEAN, M D, D Sc, Professor of Medicine in the University of London, St Thomas's Hospital; and IDA SMEDLEY MACLEAN, D.Sc, F I C London. Longmans Green and Co, Ltd. 1927. Pp 220. 10s 6d.

THIS volume of the well-known series of monographs on biochemistry deals with the lipin side of the chemistry of the fats, and with their biological significance Together with the monograph on the fats by Leathes and Raper it forms a complete and up-to-date account of these problems Fortunately for students and others the authors have followed the same system of nomenclature as did Leathes and Raper, and the monographs can thus be read together with profit

The book is divided into seven parts, the first of which introduces the subject with an explanation of the nomenclature and a classification of the lipins The several groups of lipins are then dealt with, together with those alleged lipins upon whose constitution there has been so much controversy. Plant lipins are also discussed, but perhaps to the general reader the most interesting section is that dealing with lipins from the biological standpoint. Here the authors have reviewed the effect of injecting lipins into the blood, the part played by the lipins in the coagulation of blood, and more fully, the function of lipins in fat metabolism The last named section is also one of particular interest In this edition the chemical side of the work has been brought completely up to date; it is noteworthy that the recent work of the American school, headed by Levene, on the structure of lecithin and kephalin, has been included.

FIFTH AVENUE HOSPITAL CLINICS.

First series New York: Paul B Hoeber, Inc. 1927. Pp. 336 $5.

IT is the custom for the staff at the Fifth Avenue Hospital, New York to meet twice a month At these meetings, which are open to all the practitioners and nurses of the city, papers are read and hospital material discussed. The reports of these meetings, together with reprints of some articles published in connexion with cases in the hospital, have been compiled into a book which it is hoped to publish annually. This first number, beautifully produced and illustrated, contains some 26 articles and over 60 photographs and illustrations The range of subjects is large and the standard uneven. An interesting account of the dietary arrangements of the hospital by Sarah Hickcox, the "supervising dietitian," is included, also a good symposium on thyroid gland diseases The "attending oral surgeon" contributes an account of the oral department, and concludes with a plea for closer cooperation with other departments Dr E J Rhodebeck gives a preliminary report on a study of urea feeding. One glaring set of misprints is unfortunate In an account of the discovery of insulin there is mentioned several times a "Dr McCloud," presumably intended to denote Prof McLeod The volume contains many interesting discussions of cases and of special points of surgical technique or pathology.

MOTHER AND UNBORN CHILD.

By SAMUEL RAYNOR MEAKER, Associate Professor of Gynæcology, Boston University School of Medicine London Baillière, Tindall and Cox Baltimore Williams and Wilkins Company 1927 Pp 207 11s 6*d*

THIS is an excellent little book of information and advice for the prospective mother It is well written, packed with sensible suggestions, and easy to understand It is to be hoped that its price, which is by no means excessive considering its value, will not prevent the middle-class prospective parent from purchasing it The earlier chapters are concerned with anatomy and physiology, the development of the fœtus is traced and then the signs and symptoms of pregnancy discussed In a very good chapter on the prediction of the baby's birthday and certain other predictions there are sections on heredity and maternal impressions which serve to clear away a lot of mediæval superstition, still persisting to a surprising degree among intelligent people The hygiene of pregnancy and certain troubles and discomforts are dealt with next in a sound fashion; the rest of the book on the arrival of the baby, the management of the new-born child, &c, is on orthodox lines. A special word of praise must be given to the chapter on the lying-in mother, this stage of maternity is too often neglected in a book of this nature, the mother being scarcely mentioned after the baby is safely born The author wisely remarks, "the ideal end-result in obstetrics is a normal baby and a perfectly healthy mother" It is only by a careful attention to the care of the mother during the puerperium that many gynæcological complaints can be avoided Advice to the mother as to the part she must play in this important and often difficult time is set out in this book more fully and clearly than in many a text-book of midwifery

HEALTH SUPERVISION AND MEDICAL INSPECTION OF SCHOOLS

By THOMAS D WOOD, A M, M D, College Physician, Adviser in Health Education, and Professor of Physical Education, Teachers' College, Columbia University, &c; and HUGH GRANT POWELL, A B, M D, Lecturer and Assistant Physician, Teachers' College, Columbia University London and Philadelphia W B Saunders Company, Ltd 1927. Pp 637. 35s

As the work of the school medical service involves little specialised medical knowledge, but mainly the application of the common stock of medical knowledge to the problem of the school-child, books on the subject naturally concentrate on the social and administrative questions which arise in this branch of public health effort The book follows this path The authors are thorough in their treatment of the problems involved and something—usually a great deal—is said about almost every difficulty which the school medical officer may encounter in his day's work Unfortunately, the social ideals and legislative and administrative procedure in America are peculiar to that country, and therefore much that can be read in this book, although interesting, is of little practical value on the eastern side of the Atlantic The authors have evidently confined their study to the writings of their own nationals and the book does not appear to have been prepared for foreign consumption As an example of the publisher's art it falls somewhat short of the usual high standard, and the style in which it is written is not very attractive It may well be, however, that the numerous examples included of forms and documents used by different States and towns in connexion with school medical work will be useful to those who are engaged in this branch of the public health service, and that they will find a good deal of pertinent matter dotted through the book

Reports and Analytical Records.

VITA-WEAT CRISP BREAD

(MANUFACTURED BY PEEK FREAN AND CO, LTD, LONDON, S E 16)

"Vita-Weat" claims to be "all the wheat nothing but wheat" and to be made from 100 per cent stone ground whole wheat The process of preparation is said to preserve all the vitamins, a statement which is probably correct so far as "B" is concerned as this is the most thermostable of these bodies Sir W Arbuthnot Lane has reported that the 100 per cent "whole wheat English crisp bread now being made in London contains just such materials as are absolutely essential to a vigorous condition of health" On analysis the following results were obtained —

Carbohydrates consisting of starch, altered starch, sugars natural to wheat, hemicelluloses, &c	71 00	per cent.
Protein	10 32	„
Moisture	4 90	„
Ash	2 60	„
Fat	7 90	„
Fibre	3 28	„
Caloric value per lb	1846	

The matter soluble in cold water amounts to 17 8 per cent, of which 2 8 is sugar derived from the wheat Since wheat contains from 2 to 3 per cent of fat it is evident that some other fat has been added during preparation It will be noted that the caloric value is high The crisp bread has a pleasant texture and flavour; it is undoubtedly a valuable foodstuff, more particularly in respect of its content of vitamin B, the deficiency of which in white bread and preparations of white flour is causing concern in medical circles

BEEFEX.

(BEEFEX, LTD, 19–20, WEST SMITHFIELD, E C)

This preparation is of a fluid consistency, dark in colour, and with a salty meat-extract flavour When analysed the following results were obtained —

Water	34 9	per cent
Total solids	65 1	„ „
Consisting of mineral matter	20 8	„ „
Meat fibre and coagulable proteins .	3 76	„ „
Albumoses and peptones . . .	8 57	„ „
Meat bases . . .	24 16	„ „

Out of the total of 20 8 per cent of mineral matter, 12 per cent was found to be sodium chloride The preservatives salicylic and boric acid were tested for with negative results The analytical results are consistent with those of a concentrated meat extract

THE LANCET.

LONDON, SATURDAY, JUNE 11, 1927

HE PREVENTION OF DIPHTHERIA IN LONDON

ST year, in addressing the Institute of Hygiene,[1] J D Rolleston drew attention to a tendency ie medical profession to regard diphtheria as ie down grade, whereas in London the disease in point of fact, shown a steady increase ig the past 15 years In the weekly returns of the strar-General and of the Metropolitan Asylums d the toll that it takes in sickness and death stands is heavier than that of any other complaint save les and pneumonia. The same is true for the al city of Canada where, though the case incie of diphtheria has been almost stationary for some s, the mortality-rate has risen sharply during the 8 months, as is shown in the figures given by Dr B NAH and Dr L M Murray from the Toronto River-Isolation Hospital[2] Yet in New York diphtheria exhibited a marked decline in recent years In city, since 1916, over 630,000 children have been d by the Schick method and more than 400,000 been immunised To this Dr Rolleston ascribed significant difference in the attack-rate, agreeing the chief medical officer of the Ministry of Health, in his report for 1925 states that "as antitoxin proved itself the best method of treatment, so unisation appears to be our best prophylactic" Ministry is so satisfied with this line of treatment prevention that it has determined to urge its tion by local authorities, but the largest of these, London County Council, despite the report on e immunisation against diphtheria, drawn up t by Dr J Graham Forbes, decided in October, , not to introduce toxin-antitoxin treatment into cheme for the care of school children and has ered since to this decision Dr Forbes's report in nded form has now been published by the Medical arch Council.[3] His figures show the incidence nortality of diphtheria to be higher in London than y other large city in Great Britain and higher that of almost any other European capital.

tween the years 1921 and 1925 there were 65,000 in London, some 4000 of them fatal, the death- being nearly 1 per 1000 of the child population r 15 Dr Forbes's charts and maps show that se relationship may in some areas be traced een the incidence of diphtheria and the density pulation and the degree of overcrowding The on municipal authorities have made little ess in promoting active immunisation; until recently Holborn was the only borough in which was any provision for it Special clinics were d last year for testing and immunising in minster and Camberwell, and this year in ord, but Holborn alone has figures to show ts work among the children under the care guardians at Mitcham In 1921 there were ses in one school of 600–700 boys, in 1922 were 32 cases, and in that year testing started, when 30 per cent were found to be positive, and of these over two-thirds (380 boys) were immunised In the year 1923–24 there was one case of diphtheria in these schools, in 1924–25 there were none, in 1925–26 there were two—being children whose parents had refused consent to immunisation In the infirmary, where immunisation was not carried out, there were 12 cases in 1924–25 and 19 cases in 1925–26 Other institutions were found to yield equally striking figures Dr Forbes surveys the whole country and gathers further figures from Europe and America The evidence is cumulative, although he is content to state that it "appears sufficiently convincing to justify the experienced opinions of all who have devoted much study to the problem, and hold that the Schick test and immunisation constitute one of the most notable advances in the sphere of preventive medicine" The problem, as he says, calls for the closest coöperation between all the authorities concerned Both toxin and toxin-antitoxin must be accurately standardised and must be derived from a trustworthy source The testing demands an exact technique and experience in reading results, but in the hands of a trained observer is simple and harmless Dr W H Park[4] was able recently to cite over 2,000,000 injections in the United States without ill-result Dr Forbes wisely lays emphasis on the necessity for using every possible precaution in the preparation and use of the material

The duration of immunity following a toxin-antitoxin injection appears to be at least six years, a period which will tide the child over the most susceptible time of its life Since immunity develops slowly after inoculation, taking six months or more to reach its acme, it is idle to postpone the measure until the disease becomes epidemic or the child has already come into contact with infection, although an immediate temporary protection, lasting about three weeks, can be secured by a small dose of antitoxin. The occasional occurrence of diphtheria in a Schick-negative individual, or in one who has been immunised, cannot be denied, but there is no doubt that the great majority of inoculated children are efficiently protected and that the very small percentage who develop the disease have it in a mild form The preventive measures recommended for London include an organised campaign by the controlling authorities, instruction to nurses, teachers, health visitors, maternity and child welfare workers, and the establishment of school clinics and special clinics at welfare centres and hospitals Since the disease falls more heavily on the children under 5 years of age, the work among mothers of infants is at the heart of the campaign The estimated cost of protecting all those now on the school rolls is between £85,000 and £100,000, which may be set against the actual cost of diphtheria to London ratepayers in the year 1921, which was estimated in the neighbourhood of £500,000 The sum of £30, which is what a diphtheritic child costs London, would protect 200 children from contracting diphtheria The Edinburgh public health department has been able to test and protect (if necessary) nearly 10,000 children for an expenditure in material of about £900 Dr A Joe remarks[5] on the willing response of the Edinburgh parent and the recent development of the campaign among the pre-school children It is not usual for London to fall behind other cities in matters of public health or child welfare, and the publication of Dr Forbes's report by the Medical Research Council will, we hope, be sufficient to secure appropriate action.

TRADITION IN MEDICINE

The influence of tradition over social progress can be illustrated in many fields by the consideration of medical history A small volume by Dr Bernhard J Stern,[1] emanating from the Faculty of Political Science in Columbia University, sets out to demonstrate how far this mode of reasoning can be employed, and although it is intended that its pages should be read in the light of previous sociological studies issued in the same series and dealing with social factors of a more conservative nature than the science of medicine ever can be, the fundamental questions put by Dr Stern show how well medicine can be made a chosen field of inquiry Premising that the term culture is used throughout the book as the equivalent of social heritage—that is of accumulated knowledge—he asks to what extent and why are innovations or changes in culture resisted, and what are the psychological and sociological factors involved He proceeds to consider these questions, and others arising directly out of them, in two ways, using the history of medicine for the source of his examples, first by an inquiry into the circumstances which retard the dissemination of new learning, and second by an examination of the various steps by which medicine has progressed These make tremendous subjects for discussion in one slender volume, but by the help of copious and detailed references the ground is fairly surveyed in a superficial manner, with excellent indications for more intensive study

The factors involved in retarding social change are mainly psychological, as Dr Stern recognises, and in emphasising the influences of persistent habit reactions, of the desire to avoid unpleasant situations, and of the fear of the unknown, he furnishes a criticism of common social procedure which is of definitely medical application Threats to economic vested interests, which he next discusses, can hardly be said to have played much part in medical developments, but in this section he treats of the power of tradition, as it is manifested in reverence for authority, leading to unwillingness to analyse new claims or to subvert recognised teaching Here all must see the pertinence of his arguments to the development of a science, and here the author makes a brave attempt to interpret the status of medicine as a science He emphasises the difficulties exemplified by various conflicts in medical theory and medical practice, where each side has been taken with equal vehemence by authorities who, he appears to assume, have been of equal competence The assumption, of course, begs the question, for in most of the necessary differences of opinion which have been manifested in the developments of progressive science the opponents were not actually of equal competence; they only appeared to be so because they were vested with equal academic authority or had been engaged in equally important researches Individually they were not equated The officials of the learned society who declined to accept clinical cases from Thomas Addison in illustration of his discoveries were not of equal competence with the discoverer, though they appeared to be, and while temporarily they may have impeded the dissemination of his views, the truth prevailed, as it will The opposition to Harvey's theory of the circulation of the blood was endorsed by many famous anatomists, but the mere fact that the attempts to confute him did not take the shape of anatomical demonstrations proves—unless we are to assume deliberate cowardice and chicanery on the part of a group of learned men—that Harvey's arguments were not really understood When they were grasped opposition ceased Similarly, Lister's main opponents in London, though standing in professional repute and by academic degrees on the same plane which he occupied, were in no sense his intellectual equals The opposition to Lister is not accurately described by Dr Stern, but it forms an excellent example of the power of tradition in the working, for the resistance to innovation was based upon the reasoning of persons who, being themselves badly informed, were betrayed into illogicality. The opponents of Lister seized upon minor errors in technique, forgetting that no innovation when first presented is entirely perfect, but the cavilling criticisms were not long effective in obscuring and discounting the importance of the discovery, or in delaying its acceptance, or in perpetuating the ancient procedures

Dr Stern concludes with a very just criticism of medical history as it at present exists, namely, that it is too much a study of biographies, so that individuals who have contributed to the development of medicine are removed from their scientific background and given an exaggerated importance While all can see that progressive changes may start with the activities of gifted individuals, the measure of their responsibility is not clear in many of the places where their names remain in association with the reform We ought to consider how far these changes might have occurred without the work of those who are accredited with the discoveries, and how far each man builds on the accumulated knowledge of others As a commentary on this possibility he gives a list of multiple discoveries and inventions in the history of medicine, which is of melancholy interest in recalling many wrangles over priority The list has been compiled from the writings of many authorities, and, although not perfect, records ample proof of the frequency with which great minds in medicine have thought alike And how should it be otherwise, considering the common training which their minds have received, and the common nature of the problems which life places before them?

◆

PERINEAL PROSTATECTOMY

In few branches of surgery has so much advance been made within recent years as in the treatment of the hypertrophied prostate The removal of adenomata of the prostate, from being an operation associated with grave risk to the patient, has become a relatively safe procedure in the hands of the experienced urologist The dangers of death from uræmia, shock, hæmorrhage, sepsis, and heart failure have been reduced to the minimum by diligent preoperative preparation, scrupulous care on the operating table, and thoughtful after-treatment Long series of operations by the suprapubic route with an almost insignificant mortality are reported by leading urinary surgeons in this country, and the results have been so good that there seems to be little need for the development of a different technique It was with great interest, therefore, that on May 23rd the Royal Society of Medicine welcomed Prof Hans Wildbolz, of Berne, who read a paper in the Urological Section upon the results of 300 prostatectomies by the perineal route He attributed his good results—0 5 per cent. of deaths—to careful study of the condition of the patient before operation and to the employment of a particular technique He does not advocate operation in the early stages of prostatic hypertrophy, as he does not think it fair to expose the patient to the slight risk entailed unless the prostatic enlargement has reached a degree at which the kidneys are suffering from back pressure or infection has taken place. Death from uræmia has been abolished almost completely by carrying out renal efficiency tests, but Prof. Wildbolz warns his colleagues against too implicit a trust in the test. Results which show that considerable damage to the kidney has taken place are not always incompatible with a successful issue; it is better, while bearing in mind the results of efficiency tests, to depend upon clinical acumen or intuition to determine whether operation should be undertaken or not. He related the history of a patient which showed well that no case, however bad, should be regarded by the surgeon as hopeless. The man was admitted to hospital in uræmic coma with convulsions; he had overflow incontinence, 260 mg. of urea in 100 c.cm. of blood, and an arterial pressure of 180 mm. Hg. Drainage was instituted, the symptoms of uræmia disappeared, the blood-urea fell to 140 mg. in three weeks and to 73 mg. in five weeks, and when it ultimately returned to normal a prostatectomy was undertaken successfully, the patient having remained well since. When preliminary drainage of the bladder is necessary Prof. Wildbolz prefers an in-dwelling catheter to the suprapubic opening, for the man with a suprapubic opening regards himself as an invalid and cannot get about his normal occupation, whereas with a catheter tied in he feels himself to be almost normal, and the weeks of waiting for the recovery of renal function are scarcely regarded by him as part of his illness.

---

[1] Social Factors in Medical Progress By Bernhard J Stern Ph D London P S King and Sons Ltd , New York Columbia University Press 1927 Pp 136 9s

Prof. Wildbolz made an interesting remark on the changes in the level of the blood-urea following perineal and suprapubic operations. After a preliminary drainage of the bladder he has found that a suprapubic operation may be followed by an increase in the blood-urea of 60 to 70 mg. during the first few days, whereas only occasionally after the perineal operation is any increase seen; often, indeed, there is a diminution in the amount of urea in the blood. This fact, if confirmed, would be a strong argument in favour of the perineal operation over the suprapubic. The advantages claimed for the former are that there is less danger of lung sequels, owing to the fact that the anterior abdominal wall is not interfered with, less strain is thrown upon the heart, and there is less shock. It is also asserted that the bleeding at the perineal operation is less, the damage to the tissues is not so great, better drainage is provided, and healing is quicker. Of the 300 cases quoted 227 had healed within two weeks and 44 within three weeks. Hæmorrhage is more completely under control with the perineal approach, at all events when, as in Prof. Wildbolz's particular method, the end of the membranous urethra is sutured to the internal meatus of the bladder—a procedure which favours the obliteration of the prostatic cavity. The disadvantages of his method are the risk of injury to the rectum and incontinence of urine. The rectum was injured in 7 of the 300 cases, but in none did permanent ill-effect arise. Incontinence of some degree occurred in 11, but the loss of control was not complete and occurred only when the intra-abdominal pressure was suddenly raised, as in coughing or sneezing or during some violent exertion. In only five patients did it last longer than four months, and in all it finally disappeared. No stricture of the urethra occurred in this series.

The results of perineal prostatectomy as practised at the Berne Surgical Clinic are certainly remarkable, although compared with the best results from the suprapubic operation there seems to be little numerical advantage; expert operators, in fact, arrive at the same degree of success by either route. The suprapubic method requires less technical ability, and by this approach the patient is not exposed to the risk of that most distressing of all complications—incontinence of urine. There would seem, however, to be cause shown for exploring anew the possibilities of perineal prostatectomy.

Annotations.

"Ne quid nimis."

BIRTHDAY HONOURS

MEDICINE is represented in various categories of honours published on H.M. The King's sixty-second birthday. Dr. Edward Farquhar Buzzard becomes a Knight Commander of the Victorian Order, while a knighthood has been conferred on Lieut.-Colonel Louis Edward Barnett, C.M.G., professor of surgery in Otago University, and on Dr. Charles James Martin, C.M.G., F.R.S., Director of the Lister Institute of London. Sir Farquhar Buzzard's eminence in all branches of neurology has equalled his early prowess in athletics. Sir Louis Barnett is one of the founders of the College of Surgeons of Australasia and presided over the recent Australasian Medical Congress held at Dunedin. Sir Charles Martin's name is associated with large schemes of preventive medicine in many parts of the British Commonwealth, and under his guidance research has borne much fruit for 20 years at the Lister Institute. In the Victorian Order Mr. Henry Linnington Martyn, surgeon-apothecary to the Royal Household at Windsor, has been appointed Commander. Major-General John Macfarlane Sloan, C.M.G., D.S.O., late R.A.M.C., and Colonel Charles Pye Oliver, C.M.G., late Territorial Army, have been made Companions of the Order of the Bath, while Lieut.-Colonel John Cyril Holdich Leicester, I.M.S., lately officiating surgeon-general to the Government of Bengal, has been made Companion of the Indian Empire. In the Order of the British Empire the title of Knight Commander has been conferred on Mr. Charles Percy Barlee Clubbe, consulting surgeon, Royal Prince Alfred Hospital, and that of Commander upon Surgeon-Captain Alfred James Hewitt, R.N., Dr. Neil Morrison Macfarlane, P.M.O., Basutoland, and upon Dr. William Marshall Philip, lately M.O.H., Colombo Municipal Council, Ceylon. The rank of Officer in the same Order has been conferred upon Surgeon-Commander Guy Leslie Buckeridge, R.N., Dr. Attalio Critien, chief Government medical officer and superintendent of public health, Malta, Dr. Charlotte Elizabeth Ferguson-Davie, in recognition of services in the Straits Settlements, Major Charles Morgan Finny, R.A.M.C., Dr. Edmund Lloyd, of the Church Missionary Society, Sudan, Dr. John Randall Phillips, senior member of the Legislative Council of Barbados, Major John Heatley Spencer, R.A.M.C., and upon Captain Harold Williamson, I.M.S., while Kobad Dhunjibhai Mugaseth, a medical practitioner of Calicut, Madras, has been made a Member. The list of Commanders of the Order of the British Empire also contains the names of Miss Joanna Margaret Cruickshank, R.R.C., matron-in-chief of Princess Mary's Royal Air Force Nursing Service, whilst among the Officers are those of Miss Harriet Lassell, matron of the Kasr-el-Aini Hospital, Cairo, Miss Sarah Lovell, head nurse of the London County Mental Hospital at Claybury, and of Miss Eliza Grace Musgrove, matron of the Devon County Mental Hospital. Membership of the Order has been conferred upon Miss Bridie Maureen Copeland, Miss Mildred Shirley Low, superintendent health visitor and inspector of midwives in Warwickshire, and upon Miss Annie Newman, head nurse of the London County Mental Hospital at Horton. The Kaisar-i-Hind Medal of the First Class has been awarded to the Rev. Caleb Davies, a graduate in science and medicine of Manchester University, for his splendid work among the Santals, one of the aboriginal jungle tribes of Bengal. Other recipients of this Medal are Dr. Ethel Adelaide Douglas, medical officer in charge of the Kinnaird Women's Hospital, Lucknow, who has recently made a survey of medical needs for the National Christian Council of India, and Dr. Carl F. Kugelberg, of the Swedish Mission, Madras. On behalf of the medical profession we tender hearty congratulations to the recipients of all these honours, not forgetting Mr George Goodchild, clerk and steward of the Hereford County Mental Hospital, and Miss Georgie May Smith, general secretary of the Official Medical History of the War.

TRACHOMA IN HOLLAND

WHEN trachoma was first recognised among the people of Holland, about the year 1860, it was given the name of "the Egyptian complaint" on the assumption that it had been introduced by Napoleon's troops. This legend fails, however, to account for its special predilection for Jews, and in particular for those dwelling in Amsterdam. In a recent note to the Hygiene Committee of the League of Nations, Dr N M Josephus Jitta[1] suggests that the history of the disease, so far as we know it, is best accounted for by the immigration of Polish Jews into the Low Countries during the eighteenth century. Most of them went to Amsterdam, probably carrying trachoma with them. In those days the Jewish immigrants belonged to that social stratum which is chiefly attacked by trachoma, and constituted a class which had little intimate contact with its fellow citizens. This hypothesis explains many obscure facts.

It was about 1880 that Prof Gunning first raised the alarm and drew attention to the serious endemic among Jewish children, in one school 75 per cent of the pupils were affected, while in schools where the children were from equally poor homes, but not Jews, the percentage was less than 1. Dr Westhoff's report to a Commission in 1885 ended with the words, "If radical measures are not taken it may be stated that in another century our citizens will be like the Egyptians, who were part-blind and among whom nobody possessed normal vision." In consequence the municipality founded an ophthalmological clinic, school teachers were warned, and various public bodies attacked the social side of the problem. The number of cases gradually declined, and with advancing civilisation the conditions under which trachoma flourishes became rarer. Nevertheless in 1913 Dr Sajet calculated that there were 1400 persons in Amsterdam with active trachoma, and another 1120 in whom the condition was latent. In the same year the Municipal Council appointed a commission to inquire into the subject, and their report was published in 1924.[2] These workers examined all the trachomatous individuals and their families that they could find through the schools and clinics. They found 8 8 per cent of Jewish school-children and 0 6 per cent of others suffering from trachoma, and of these the great majority had no functional disturbance and had never had any treatment. To oculists accustomed to deal with grave cases this was naturally a shock. They found further that if the children were treated in this early stage they were cured quite easily and without corneal complications. Their charts show that most children are infected before their sixth year and that contagion at school is not an important ætiological factor. Thus the source of infection is essentially in the home, generally the mother. The provision of special schools would therefore be of little use in checking the endemic. In 1918 a special clinic was opened in the Jewish quarter, an oculist was appointed to inspect public schools, and untreated trachomatous children were forbidden to attend school. In 1921 results began to appear, and for the next two years the numbers attending at the clinic steadily declined. Moreover, of the 31 children classed as "cured" in 1922, only one had visual defect due to corneal involvement. The treatment at the clinic began with expression of the granulations under cocaine-adrenalin, together with firm massage to the extent of drawing a few droplets of blood. Silver nitrate or ichthargan was then instilled, and most cases were cured without admission to hospital. Dr. Jitta's note brings this story up to date. The diminution in cases has continued, so that in 1925 only 18 new cases were detected. It thus appears that 50 years of strenuous spade-work, patience, and perseverance have had their reward, and that Amsterdam has made it clear that where trachoma is not truly endemic, but imported, and maintained by conditions of poverty and dirt, it can be effectively combated.

RESISTANCE TO THE METASTATIC SPREAD OF CANCER.

ONE recent development of cancer research—viz., the experimental production of cancer by various forms of chronic irritation—dates from the well-known work done on spiroptera cancer by Prof Johannes Fibiger, of Copenhagen. Prof Fibiger has now published, in conjunction with Dr. P Møller, the results of an important investigation entitled Investigations upon Immunisation against Metastasis Formation in Experimental Cancer.[1] Twenty years ago it was shown that if a transplanted tumour underwent absorption the animal which had carried that tumour could not again be inoculated successfully with a transplantable neoplasm. This phenomenon was described as "immunity" or "resistance." The same condition could be induced by the injection of normal cells of the same species, embryo skin being a particularly active "immunising" agent. These observations naturally aroused great expectations at the time, because they seemed to offer the possibility of immunising an organism against cancer. It was soon found, however, that cancer spontaneously arose in animals which had been immunised. Since the number of cases in which this could be observed was for obvious reasons very small, it was necessary to test this important point again in animals in which cancer could be produced experimentally. The present paper records observations on 293 mice, which were tarred on alternate days for four months. Of these mice, 156 received injections of embryo skin emulsion during the process of tarring, while the remaining 137 mice were kept as controls. The same number of tar tumours appeared in both groups and at approximately the same time. This result confirms the earlier observations in showing that "immunisation" is no protection against the genesis of a new tumour. But when the formation of metastases in these experiments was examined it was found that in the immunised mice only half the number showed metastatic spread as compared with the control mice. In the latter group metastases were found in 58 per cent. of the cancerous mice, while the immunised mice showed metastases in only 30 per cent. of the cancerous animals. The authors make a special point of warning their readers against the premature therapeutic application of these results to human cancer. The nature of this process of immunisation is still very obscure, but the conclusion seems justified from these observations that in the metastatic spread of malignant cells the organism does not play merely a passive part, but is capable of offering an active resistance.

THE RELATION OF TEMPERATURE AND PULSE-RATE IN DISEASE.

THE introduction of increasingly trustworthy laboratory methods of diagnosis in febrile illnesses is said to lead to some degree of carelessness in clinical observation. There remains, happily, a host of careful clinicians who guard against this tendency themselves and check the medical student's besetting sin of piecing together reports. In the *Medical Journal of Australia* for April 2nd Prof D. W Carmalt-Jones, of the University of Otago, N Z, contributes an interesting series of clinical observations on the relation of temperature and pulse-rate in disease After illustrating the close correspondence between the pulse-rate and the temperature chart when both are plotted in acute infectious diseases, he emphasises the clinical significance which attaches to deviations from this rule It is assuredly true that though the clinical thermometer supplies a means of graphically recording the body's response to infection with a relatively small margin of error on the part of the observer, the pulse-rate will frequently give warning of grave complications, especially of a myocardial nature, which may be overlooked if the temperature chart alone is considered During the influenza epidemic of 1918, when cases were admitted to military hospitals in thousands daily, it was a common experience that selection for immediate special treatment of those patients who exhibited marked pyrexia was a very poor guide to the real gravity of the cases, whereas an experienced nurse could, by observation of the pulse-rate, pick out the more serious cases with a high degree of accuracy In surgical practice this aspect of clinical observation has long been recognised, a rising pulse with a falling temperature being, as Prof Carmalt-Jones points out, of the gravest significance In some hospitals it has been found that in cases of suspected spreading peritonitis the surest guide during the hours immediately following admission is to keep a record of the pulse-rate every half hour, without reference to the temperature, and on this indication alone early and successful operation has been performed at a time when the other clinical signs remained doubtful In more chronic pyrexial conditions it is as a guide to the condition of the myocardium that a pulse chart becomes most useful. In cases of good resistance in which recovery occurs without damage to the heart muscle, the pulse-rate falls with the temperature, and any delay in the fall of the pulse-rate relative to the temperature is in proportion to the myocardial damage done It remains to be recognised that pulse-rate records require more care on the part of the observer than do similar records of temperature Even a junior nurse will look twice at her thermometer, and possibly take the patient's temperature again, when the reading is in any way surprising, but we have again and again been struck by the unwondering calmness with which a normal pulse-rate is recorded by an otherwise skilful nurse in cases of heart failure, where only a proportion of ventricular pulsations is in reality reaching her fingers over the radial artery This is a point which seems to escape proper comment in many teaching hospitals, and it is one which Prof Carmalt-Jones might well have stressed in his paper In continental hospitals the daily volume of urine secreted is sometimes used as the most accurate index of the cardiac function, again, accuracy and simplicity of recording are the criteria which must decide the utility of the method, and again it must be admitted that, like pulse charts, urine charts are not as easy to obtain as are the more familiar records at the bedside.

THERMOPHILIC BACTERIA IN MILK

As our knowledge of bacteriology extends we are finding the range for bacterial growth, both in relation to temperature and to other environmental conditions, greater than was once supposed possible There are, for example, halophilic bacteria which flourish in solutions of salt, inimical for most bacteria Another interesting group is that of the thermophilic bacteria whose optimal growth temperature is well above normal body temperature and is generally in the neighbourhood of 55° C While this group is of no direct significance in human pathology, it is of some importance in commercial processes, particularly in relation to canned foodstuffs. In a recent paper[1] Miss Eckford discusses the significance of thermophilic bacteria in milk A distinction must be drawn between true or obligate thermophiles with a range of growth from 42° to 70° C and an optimal growth temperature of 50° to 60° C, and facultative thermophiles which grow best at 37° C or other lower temperatures, but which can also grow at 55° C Many of the common sporing aerobes, such as *B mesentericus* or *B subtilis*, can accommodate their growth to the higher temperature The author introduces a third group, the thermotolerant bacilli, which grow best at the higher temperatures but which can grow at blood heat All the strains studied from the Baltimore milk-supplies were aerobic spore-bearing bacilli Their ability to cause decomposition changes in foods depends on the extent to which they possess proteolytic and fermentative properties While most can liquefy gelatin and some produce acid from sugars, none caused gaseous fermentation and their proteolytic powers were absent or slight They are not likely to be a cause of decomposition changes in canned foods or to alter milk, although some of the isolated strains grown in milk at 55° C in pure culture were able to coagulate it They have some significance in connexion with pasteurisation, since they survive this treatment The obligate thermophiles were found not to multiply in milk at 62° C On the other hand, the thermotolerant types multiplied greatly at this high temperature and particularly at 55° C These strains, therefore, may cause trouble to pasteurising plants by multiplying during the process and giving the milk a high count They may cause pin-point colonies at 37° C Their existence is one of the causes of high counts after pasteurisation, a condition which occurs from time to time Sweetened and unsweetened canned milk tins were investigated but no true thermophiles were found in them The only organisms which developed at 55° C were bacilli of the mesentericus-subtilis group, This is in accord with the findings of J Weinzirl in U S A, although W G Savage and R F Hunwicke in England found obligate thermophiles in sweetened milk in a number of instances and one strain in unsweetened milk These strains were, however, unable to initiate unsoundness and were regarded as of no practical importance by their discoverers The only exception at present to the view that thermophilic bacteria are not a cause of decomposition changes in foodstuffs is the observation by E J Cameron and J R Esty (1926) of unsoundness changes from this cause in canned corn and other vegetables, giving rise to what they call "flat sour" spoilage

A COMPREHENSIVE STUDY OF POSTURE.

The subject of correct posture and of departures from it and their treatment has received far more attention in the United States of America than in this country, or indeed, in Europe generally. In the U S Public Health Reports this subject has been recently reviewed[1] by Dr Louis Schwartz, who gives a bibliographical list of 154 publications, beginning with the quaint "Anthropometamorphosis" by John Bulwer, of 1650, but not including some articles on the subject which have been published in the last year or two in our pages and elsewhere in this country Some orthopædic surgeons in the United States have attributed far-reaching pathological results to faulty habits of standing and sitting, and the existence of an American Posture League testifies to the place such matters occupy in the public attention In this country faulty posture is regarded as the result rather than as the cause of illness, and due to a general weakness and lack of postural tone in the skeletal muscles Too much, perhaps, has been made by some writers of the contrast between the spinal curves of the quadrupeds and anthropoids on the one hand and of man on the other. In a paper published in 1886 D J Cunningham showed[2] that these differences are not great. The lumbar curve was found to be present in a well marked form not only in chimpanzees, but also in most of the lower apes and even under certain conditions in some quadrupeds—e.g., the bear. Writers on posture are apt to assume that the anthropoid apes habitually adopt the quadrupedal attitude and mode of progression. Yet a glance at the illustrations in W. Kohler's "Mentality of Apes"[3] will show that in none of the six plates of the various activities of chimpanzees is a single ape on all fours. The value of the three curves of the spinal column as a composite spring, which absorbs shocks transmitted through the lower extremities towards the cranium and brain, seems to have been overlooked by most writers on this subject. Dr. Schwartz summarises the position thus:—

[1] M O Eckford Amer Jour of Hygiene, 1927, vii, 201

[1] A Résumé with Comments of the Available Literature relating to Posture, by Louis Schwartz, Surgeon, United States Public Health Service, Washington, May 6th 1927

[2] The Lumbar Curves in Man and Apes, by D J. Cunningham A paper read before the Dublin Academy and abstracted in Nature, 1886, xxxiii, 378

1. There is a lack of agreement in the various definitions of standards and tests for good posture.
2. Heredity, type of build, balance of muscle strength, and tone have not been given sufficient importance in establishing standards for posture.
3. It has not been established whether the faulty postures associated with certain diseases are the causes or the results of these diseases.
4. There is no universally satisfactory test for physical fitness.

The bibliography should be useful to students and future writers upon this subject.

FLUID TENSION IN THE EYE

THE thesis which Dr. W. S. Duke-Elder[4] sets out to demonstrate in an important monograph is this: that the nature of the mechanism of the formation and circulation of the aqueous humour, as at present classically accepted and taught, is wrong. The aqueous, he contends, is neither a secretion, nor in the accepted sense a transudate from the blood; it is a dialysate from the capillary plasma, the essential dialysing membrane being the capillary walls. Under normal conditions, while an interchange due to metabolic activity constantly occurs, and an internal thermic current exists, the aqueous humour does not circulate actively through the eye, but is in equilibrium with the capillary blood; at the same time constantly occurring changes of pressure, induced by muscular movements, &c., superimpose upon it secondarily a minimal and intermittent circulation. We have quoted the author's own words because no condensation of them would give a correct idea of his thesis, which he supports by arguments based on the general chemical composition and physical properties of the aqueous both in normal and abnormal states. That the phenomenon of intraocular pressure is not to be explained by a specific secretory force is proved, the author maintains, by the fact that even the excised eye has a tension of 8 to 10 mm. Hg, which it retains for some considerable time and only loses gradually on the disintegration of the lining cells. There must be a lining structure which acts as a relatively waterproof membrane, and it is suggested that such a membrane is formed by the endothelium of the cornea, the endothelium and epithelium covering the iris and ciliary body, and the retinal epithelium supported by the membrane of Bruch. It is further suggested that the aqueous humour, being in thermodynamic equilibrium with the capillary blood, is without an active circulation in the generally accepted sense of the term, but that it is essentially stagnant, apart from the osmotic interchange of the constituents of the two fluids and apart from an intermittent circulation due to the activity of the external and internal musculature, assisted probably by the rhythmic variations of the ocular pulse. The canal of Schlemm acts as a safety-valve mechanism to aid in the maintenance of the intraocular pressure at its normal level. The author supports his argument by the results of the histological method of injection and of physiological experiment. The view that the aqueous is a secretion from glands in the ciliary body may be traced to the papers published more than 30 years ago by Treacher Collins, but Dr. Duke-Elder combats the idea that these so-called glands have any secretory function. The rival theory, that the aqueous is formed by a pressure transudation from the ciliary body, that it circulates through the eye, and finds exit by the canal of Schlemm is also examined and found wanting. The theory suggested is that the intraocular fluid is a simple dialysate from the capillary blood, the dialysing membrane being the capillary walls. There is perhaps no part of ocular physiology that has given rise to more controversy than this, as may be judged by the copious bibliography which is appended to this essay. Its practical bearing is by no means slight, especially in connexion with the pathology of glaucoma and of cataract. This paper is well calculated to serve as a challenge to those who hold to the older theories, and it will doubtless receive the attention that it deserves.

AN INTERNATIONAL ENCYCLOPÆDIA OF INDUSTRIAL HYGIENE.

TWO further fascicles have reached us of "Occupation and Health," which is being published in sections, from Geneva by the International Labour Office. These covers contain 11 articles, bringing the total issued so far up to 68. The work is appearing simultaneously in French and English, while the original articles may have been written in Spanish, Italian, German, or Dutch, according to the nationality of the authors. At times evidence appears of difficulties with translation, such are inevitable when highly technical processes are being described, but they are commendably few. The most important of the new articles are those dealing with tuberculosis and silicosis, miners' nystagmus, coal-miners' diseases, and the woollen industry. In each case the contributions to knowledge made by British investigators are noted—indeed, they form the foundation of each article. Thus the findings of the British Committee on Miners' Nystagmus are carefully stated and accepted regarding this disease and its prevention—viz., that more light, always more light, is needed at the bottom of the mine. The article dealing with this subject is excellent and quite up to date. The most weighty of the new articles is that dealing with the influence of industrialism upon the prevalence of tuberculosis. Statistics drawn from many sources are used to support the argument maintained, that three factors determine the incidence of tuberculous infection—namely, the individual, his environment, and his occupation. In this article it is unfortunate that the curve belonging to age-period 15–19 is ascribed to age-period 50–59 and vice versa. Reference is made to the influence, from the occupational point of view, of opportunities for infection, of alcoholism, and, in particular, of the specific effect exerted by inhaling silica dust. The subject of silicosis in reference to pulmonary tuberculosis is here concisely stated and brought up to date. The article dealing with coal-miners' diseases (apart from nystagmus) contains illustrations of men at work in continental coal-mines, and statistics of coal-mining and the diseases associated with it in various parts of the world, including Great Britain. Although the figures are not all presented in the same way, which may lead to difficulty in grasping their full significance, there appears no reason to doubt that coal-miners as a whole suffer little from tuberculosis, but much from other respiratory diseases, while they have something like a monopoly of septic infections of the palm of the hand and of the knee. Their high death-rate from accident holds good all over the world, increasing with the depth of the mine. Fortunately, preventive measures have kept British accident figures below those of most other countries.

THE DOUBTFUL VALUE OF ISOLATION IN SCARLATINA

The recent claims of Dr. C Chapin, of Providence, U S.A , with regard to the importance of the isolation of cases of scarlatina, have drawn a statistically-armed reply from Dr Peter M. Holst in the *Tidsskrift for Den Norske Laegeforening* for April 15th According to Dr. Chapin, isolation of cases of scarlatina means, in practice, the isolation of most of the severe cases, whereas many light cases not only escape isolation but also the diagnosis and treatment of a doctor He suggests that the most severe cases represent particularly virulent strains of organisms, and that the consistent isolation of these severe cases has helped to suppress such virulent strains; further, that in this hypothesis is to be found at any rate a partial explanation of the tendency scarlatina has shown of late to become a comparatively harmless disease His statistical material is handled so as to show that the decline of virulence of scarlatina has gone hand in hand with hospitalisation In his criticism of this teaching, Dr Holst points out that the great decline in the mortality from scarlatina in Norway occurred ten years before it was demonstrable in Sweden, although no one could claim that this difference was due to isolation being more effective in Norway. In 1880 the mortality from scarlatina in Norway was 13 6 per cent In Sweden in the same period it was 17 per cent In 1895 it was 3 9 per cent in Norway and 6 8 per cent in Sweden In 1907 Trodhjem, in 1910 Bergen, and in 1921 Stavanger abandoned the isolation and hospitalisation which had hitherto been enforced in cases of scarlatina, putting it, except in some details, in the same category as measles and whooping-cough In Oslo, however, the old regulations with regard to isolation and hospitalisation are still in force, and a comparison of Oslo with Bergen with regard to the incidence of the disease shows that the former has uniformly suffered much more than the latter In the five-year period 1900–04 the mortality from scarlatina was 1 8 per cent in Bergen and 3 3 per cent. in Oslo, the morbidity being also considerably higher in Oslo In the five-year period 1915–19 the morbidity in the two towns showed the same great difference, and while the mortality was only 1 per cent. in Bergen, it was 1 9 per cent in Oslo After referring to the experience of Helsingfors, where hospitalisation has failed to achieve results commensurate with the cost thereof,[1] Dr Holst concludes that the case for enforcing costly hospitalisation for scarlatina at the present time is not proven

THE CAUSE OF RHEUMATOID ARTHRITIS

Nothing useful is known of the causes which lead up to the first attack of rheumatoid arthritis It may, and often does, affect a single individual in a family among whom it is impossible to distinguish any difference of constitution, dietetic proclivity, or exposure to infection What is known of the disease is the inexorableness of its course when it has once started; it is as though a person should have complete prevision of the future with total loss of memory of the past The discussion, which took place at the Section of Comparative Medicine of the Royal Society of Medicine on May 25th, was postponed for a week in order to give opportunity to the very large number of speakers who desired to take part in it , but, searching as was the discussion, it may be held to have laid bare our ignorance rather than to have contributed to our knowledge There were advocates present of the principal ætiological theories in which the condition is regarded as primarily infective or primarily nutritional The evidence adduced was for the most part mutually destructive If, for example, the disease were due directly or indirectly to deficient nutrition surely its progress could be arrested by the diet rich in vitamins which is one of the first prescriptions of any modern doctor called in to treat any chronic ailment of obscure origin The large class of cases showing pyrexia, enlargement of the spleen, and inflammatory exudate strongly suggests an infective condition at some stage of the disease , yet the argument that if due to infection the disease would surely be more common among those who live poorly and closely together is not easy to answer Dr M J Rowlands, who introduced the discussion, produced evidence of the sterility of the synovial fluid in 40 cases of rheumatism and rheumatic arthritis examined by him in 1914–15 and of the association of a similar condition in animals with a colon bacillus infection of the urine In the course of the discussion prominent biochemists pointed to the lowered resistance to infection brought about both in animals and human beings by serious deficiency in certain accessory factors of food It seems, in fact, to be almost the rule when vitamin A is deficient Deficiency of vitamin B, on the other hand, produces some change in the lymphoid tissue and some thinning of the intestinal wall which may be a prelude to the diffusion of bacterial poison from the alimentary canal The growing evidence of the composite character of vitamin B should, however, render us chary of drawing any definite conclusion from the evidence as at present before us It may be that all the morbid changes observed in various cases, including the bacilluria and the intestinal toxæmia, are the effect and not the cause of the rheumatoid condition Such a discussion may have value, but rather in the direction of stimulating controlled research than in building up a framework of facile theory

A PIONEER IN IMMUNOLOGY.

It is announced that Dr. Abraham Zingher died on Sunday last in a laboratory at the Willard Parker Hospital, New York, being asphyxiated by coal-gas which had escaped unnoticed from a bunsen burner Dr Zingher was assistant professor of hygiene in the University of New York and had spent most of his professional life in that city He was in his forty-second year, and graduated from Cornell University College in 1908 For the last ten years he had been associated with Dr W. H. Park, to whom he was assistant, and these workers have done a great deal towards the introduction of Schick-testing and active immunisation against diphtheria It is primarily owing to their efforts that these measures have been accepted by the medical profession and the public, and their success is shown by the fact that some 2 million inoculations have been carried out in New York A campaign has been set on foot to rid the city of diphtheria by 1930, and should reasonable success attend this attempt the result will be a splendid monument to the work stimulated from the Willard Parker Hospital Besides this Dr Zingher's name will be associated with the research on scarlet fever, for he investigated the use of the Dick test and of antitoxin and studied active immunisation against the disease With the natural zeal of the keen man he had here, perhaps, shown a slight tendency to accept conclusions without demanding such a weight of evidence as was needed to satisfy him in the earlier research on diphtheria All this recent work owes much to him, however, and many European visitors to New York will gratefully remember Dr Zingher's enthusiasm and ready courtesy in arranging to demonstrate the work of testing and inoculation that was going on under his direction

HOSPITALS AND PANEL PATIENTS

That there is not only a " bottle of medicine habit," but a hospital habit has become increasingly evident since the war The great extension of hospital facilities for the treatment of disease during the last few years has induced many people who are quite well able to pay for ordinary medical attention to resort to the voluntary hospitals, and the consequence is that, to say nothing of waiting-lists for beds, almost every out-patient department is seriously congested If one patient involved only one attendance the difficulty might be soluble, but the great voluntary institutions now count their out-patient attendances by tens of thousands in a year, and the strain is becoming too heavy to be borne either by finance or physical accommodation It is therefore not surprising that the London Hospital should have decided to place some limits to its readiness to treat all comers In future it will rule out panel patients altogether, save when they produce a letter from their panel doctor stating why the help of the hospital is required In view of the necessary limitations of panel practice many such occasions must arise though their proportion should be small. For the increasing tendency of this type of patient to resort to the hospitals no responsibility rests upon the panel doctor The increase year by year in the number of prescriptions issued to insured persons bears witness to the fact that the panel doctor is taking the lion's share in the treatment of trivial illness In the majority of cases the panel doctor does not send his patients to hospital; he is, in fact, usually unaware of their action But it is obviously unfair and unreasonable to expect a hospital to do for nothing work for which the panel practitioner is paid, and it was assuredly never the intention of the originators of health insurance legislation that the beneficiary should be able to flit at his own good pleasure from his private doctor to the nearest hospital when his ailment is such as to come well within the limits of medical benefit The experience of the London Hospital is that it is being constantly asked to treat trivial illnesses which fall naturally within the province of the panel doctor, and it is performing a public service in refusing any longer to be made the victim of what is usually little better than caprice It is not only not shutting its doors to any genuine "hospital case," but is augmenting its power of dealing with such cases by barring the relatively unimportant

THE Registrar-General's Statistical Review of England and Wales for the year 1925 has been completed by the issue of Part III Text, which is now on sale at H M Stationery Office, price 5s This contains the official analysis of the vital statistics contained in Parts I (Medical) and II (Civil), issued last year

The Services.

ROYAL ARMY MEDICAL CORPS

Lt-Col J G Foster, having attained the age for retirement, retires on retd pay

Maj E H M Moore to be Lt-Col, vice Lt.-Col J G Foster

Capts to be Majs K M Nelson and D McVicker

Lt K Fletcher-Barrett to be Capt

H T Chiswell to be Temp Lt

MILITIA

Maj H K Ward relinquishes his commn and retains the rank of Maj

TERRITORIAL ARMY

Maj J Taylor resigns his commn and retains his rank

Maj H N. Burroughes, having attained the age limit, is ret and granted the rank of Lt.-Col with permission to wear the prescribed uniform

Capt. V H Wardle to be Maj

COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS

A limited number of commissions in the Royal Army Medical Corps will be offered by nomination in July Candidates, who must be under 28 years of age on August 1st, should submit their applications, not later than July 15th, to the Under-Secretary of State, the War Office (A M D 1), Whitehall, London, from whom further particulars may be obtained.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXXVII.

THE TREATMENT OF FEMORAL HERNIA.

THE treatment of femoral hernia is governed by two factors First, it is anatomically impossible to control the neck of the sac from without, palliative treatment by a truss is therefore at best unsatisfactory. Secondly, strangulation is more frequent than in any other variety of external hernia, and when it occurs is of a more dangerous type For these reasons treatment by operation is, in most cases, the wiser course Advanced age or disease may render any operation inadvisable, but the risks of a general anæsthetic may be avoided by the use of local anæsthesia, which is particularly well suited to operations upon femoral and inguinal herniæ Treatment by a truss is less objectionable in the larger herniæ Where the sac is lax and a good impulse is felt on coughing, and where the canal is large enough to admit two fingers, the risks of strangulation are very much less than in the common type of hernia which is small, tense, and gives hardly any impulse on coughing In large herniæ, however, it is difficult to find a truss which can be tolerated by the patient

The majority of femoral herniæ are irreducible from their first appearance, if the attempt succeeds, there is no tendency for the contents to remain reduced, for the crural ring, once forced, remains patent owing to ligamentous nature of its boundaries It is impossible to apply any pressure which will effectively keep the peritoneal sac closed The mass which can be felt in Scarpa's triangle in these cases consists for the most part of alternating membranous and fatty coats, a swelling the size of a walnut will usually contain a sac no larger than the last phalanx of the little finger When such a sac has been emptied, only the contents are returned to the abdomen, and the coverings remain as an elastic mass in Scarpa's triangle The small sac lying in this mass cannot be effectively controlled by the pad of the truss The funnel shaped neck lies deeply under the inner end of Poupart's ligament, and must always remain open, inviting recurrence.

Again, a femoral truss can neither be kept in place nor worn with comfort. Movements of the body occur around certain planes, and leave their impress on the surface as flexure lines upon the skin of which the creases in the palm are the best-known examples The flexure line corresponding to movements between thigh and trunk, well seen in the obese, runs transversely across Scarpa's triangle from the pubic spine on the inner side to the region of the top of the great trochanter The pad of an inguinal truss lies wholly above this line, and moves with the trunk. The pad of a femoral truss must lie athwart it, and can therefore never rest firmly on subadjacent parts, or be free from discomfort.

The frequency of strangulation in femoral hernia is accounted for by the unyielding nature of the structures surrounding the neck When strangulation occurs, these same factors lead to early gangrene and perforation of the intestine Further, the symptoms of strangulation may not be associated by the patient with the presence of a femoral hernia, which she knows to be there Zachary Cope has observed that the peritoneum of the posterior abdominal wall, from which the sac of a femoral hernia is derived, is less sensitive than the anterior abdominal peritoneum which lines an inguinal sac Localised pain is sometimes so inconspicuous that the patient may mistake the vomiting and colic of a strangulation for symptoms of food poisoning, and may take an aperient, making matters infinitely worse

For these two reasons, the inefficacy of the truss and the danger of strangulation, the patient should be advised to submit to operation unless there are cogent reasons for avoiding this course

Type of Operation.

An operation designed for the radical cure of any hernia should fulfil three requirements the isolation and emptying of the peritoneal sac, the closure of the sac at its neck, and the repair of the hernial opening at its commencement, in order to prevent the formation of a fresh sac

The special features of femoral hernia are concerned with the character of the hernial opening The crural canal, along which a femoral hernia passes, is a compartment of the femoral sheath, and its wall is derived from the fasciæ lining the abdominal cavity. It is closed above by a fibrous diaphragm, the septum crurale. Normally it contains loose fat. It transmits a number of lymphatic vessels, by which lymph passes from the deeper subfascial inguinal glands surrounding the femoral vein to the external iliac group of abdominal lymph glands. It also acts as a resilient washer lying beside the femoral vein as it passes under Poupart's ligament, and allowing that vessel to expand when, under conditions of muscular exercise, the volume of blood returning along it may increase as much as eight- to ten-fold. Because of this relationship to the femoral vein, any method of closure which fastens down the inner end of Poupart's ligament to the pubis, whether by suture or by a metal staple, is unsound. Such a procedure depresses the ligament along its whole length, and makes it constrict the femoral vein. Moreover, as this ligament is an integral part of the attachment of the abdominal musculature, it will not remain in its new position. Stitches cut out, while staples are apt to work loose from the bone and so cause serious trouble.

The operations for femoral hernia are of two main types: those where the sac is approached from above Poupart's ligament through the inguinal canal, and those where it is approached directly from Scarpa's triangle. The former approach allows the sac to be tied off at its neck, and is also satisfactory from the point of view of closure of the canal, but it does not permit the isolation of the sac from its surroundings. In the operation performed entirely from above, the whole sac with all its coverings has to be pulled under Poupart's ligament into the inguinal incision, thereby tearing an unnecessarily large hole in the fibrous structures of the canal and rendering closure difficult. It is only necessary to remove the peritoneal sac. The remaining coverings should be left undisturbed in the crural canal, as they help in the obliteration of the space.

The approach from below does not permit direct access to the neck of the sac. The wall of the bladder is not uncommonly drawn down into the crural canal on the inner side of an old-standing hernia, and can only be stripped off the neck of the sac with some difficulty. If the surrounding tissues have been cleared without the aid of direct inspection, it is very easy to include the bladder in the stitch which transfixes the neck of the sac, or even to cut away part of its wall. The combined route is therefore preferable in all cases.

The Standard Operation

1. An incision is made along the line of the inguinal canal, and is then carried vertically downwards for 2 inches over the saphenous opening. As in all curved incisions, it is advisable to scratch the skin transversely before cutting in order to ensure accurate approximation afterwards. The wound is deepened to expose the external oblique over the length of the inguinal canal, the inner end of Poupart's ligament, and the coverings of the femoral sac. Cutaneous vessels, which are very numerous, are secured with pressure forceps as they are encountered, and tied off.

2. The coverings of the hernia are now divided in turn with Mayo scissors till the peritoneal sac is opened. The interior is inspected, and any contents returned to the abdomen. If they are adherent at the neck no attempt is made to detach them till later. The edges of the sac are caught with fine forceps, and all coverings stripped off by blunt dissection till the peritoneal sac is freed right up into the crural canal. The neck is clamped with a pair of artery forceps and the remainder of the sac cut away.

3. The inguinal canal is now opened by incising first the external oblique and then the cremaster muscle. The cord or round ligament is lifted from its bed and held out of the way in the loop of a pair of tissue forceps, exposing the posterior wall of the inguinal canal consisting of transversalis fascia. This is incised immediately above and parallel to Poupart's ligament. If the forceps which grasp the neck of the sac are now thrust upwards the latter is pushed up into view through the soft extraperitoneal fat. The forceps are then removed, the neck caught up, and brought into the wound. In this situation it is very easy to free any omentum which is adherent, and, by trimming the edges, to close the opening in such a manner that no dimple is left on the abdominal surface of the peritoneum.

4. The hernial opening is now closed at its abdominal end by extending the attachment of the conjoined tendon further along the ilio-pectineal line, so that it lies close to the femoral vein, and interposes a barrier of muscle between the abdominal cavity and the crural canal. The crural canal itself is reinforced by drawing the fatty coverings of the sac into the empty space left by its removal. With the right hand two or three mattress sutures of stout catgut are passed first through the lower edge of the conjoined tendon, then through Astley Cooper's ligament (the thickened upper edge of the pectineus fascia on the ilio-pectineal line), then down through the crural canal into the fatty coverings of the sac which have been left in situ, then back through the crural canal to the conjoined tendon. Meanwhile the forefinger of the left hand is kept on the femoral vein, pressing it outwards out of the way. When these sutures are tied, the lower edge of the conjoined tendon is drawn down to the pelvic brim just inside the femoral vein, and a fatty plug from the saphenous opening is drawn up under Poupart's ligament, forming a firm yet resilient pad.

5. The cord is now replaced, the cremaster and external oblique muscles sutured, and the skin wound closed.

Operation in Large or Recurrent Hernia

In old-standing femoral herniæ, or in those which have recurred after operation, the peritoneum and its coverings become adherent to all structures under Poupart's ligament, so that satisfactory isolation of the neck from below is impossible. In such cases, after exposing and opening the sac as in the standard operation, Poupart's ligament should be divided ¼ of an inch from its pubic attachment and thrown outwards. This procedure makes the exposure of the peritoneum and repair of the canal much more easy, and, in a difficult case, involves much less damage than an attempt to clear an adherent sac from below. Division of Poupart's ligament is better than detachment of the pubic spine. No disability follows if the ligament is carefully sutured at the end of operation.

In some old femoral herniæ the protrusion becomes so large that Poupart's ligament is dislocated forwards, and the neck of the sac comes to lie in front of, as well as internal to, the femoral vessels. The method of repair outlined above is not sufficient in such cases. After removal of the sac and closure of the peritoneum by the inguinal route, the weak area must be repaired with strips of fascia lata ¼ inch wide, and taken from the whole length of the thigh. Gallie's needle as sold for plastic operations with fascia lata is too large for this operation, and a similar needle only an eighth of an inch wide is better. The fascial strips are passed from the conjoined tendon down to Astley Cooper's ligament, up through the edge of Poupart's ligament, and then back to the conjoined tendon. This suture is continued inwards until the whole weak area is bridged by a lacing of fascial strips, only allowing comfortable room for the femoral vein and artery to pass into the thigh. No attempt should be made to draw the fascial bands tight, they protect the gap by their own strength rather than by drawing surrounding parts together. This method has proved very successful even in large and old-established femoral herniæ.

Femoral Hernia in Childhood.—While the majority of femoral herniæ are seen in adult women who have borne children, they may also occur in childhood. Before puberty the incidence in both sexes is the same, and such herniæ probably occur in congenital sacs. In these the sac may be closed from below, and Gimbernat's ligament sewn to the fascia over the pectineus. It is better, however, to operate by the combined route as in adults.

There are only two *complications* of importance—injury to bladder and thrombosis of femoral vein.

Gross injury to the bladder is very unlikely to occur if the operation is carried out by the combined route. Slight hæmaturia occurring on the day after operation may be due to disturbance of the wall of the bladder by blunt dissection, or possibly to a stitch having penetrated part of the musculature. If the condition of the wound is satisfactory, a catheter should be tied into the urethra for 48 hours, to prevent any overfilling of the bladder and tension of its walls.

Thrombosis of the femoral vein is due to injury of the wall of the vessel. It is perhaps more likely to occur after the operation performed entirely through the inguinal canal, as the dislocation of the sac from above involves forcible pulling upon structures which are firmly adherent to the vein. Clean dissection lessens the risk of thrombosis. Stagnation of the circulation is a contributory factor, and for this reason gentle daily massage to the thigh should be employed and movements of the limb encouraged during the immediate post-operative period.

INTER-STATE POST-GRADUATE ASSEMBLY OF NORTH AMERICA

VISIT TO LONDON, JUNE 1ST–3RD, 1927

LAST week we reported the inaugural session of the congress held in London by a large number of medical men from the United States and Canada who are visiting this country under the auspices of the North American Post-Graduate Assembly During the congress a series of short lectures were given by Sir Crisp English, Dr Murray Levick, Dr L S T. Burrell, Mr H D Gillies, Mr. W E Miles, Prof. Hugh MacLean, Mr T P Dunhill, Mr H W. Carson, and Sir StClair Thomson On Thursday a demonstration was given in the museum of the Royal College of Surgeons, and on Friday evening there was a reception at the Royal Society of Medicine The papers which follow are among those which were read at the congress The contributions of Sir Crisp English and Dr L S T Burrell appeared in our columns last week

THE POST-FEBRILE TREATMENT OF INFANTILE PARALYSIS

BY G MURRAY LEVICK, M.R C S.

THE post-febrile treatment of infantile paralysis requires special knowledge of several branches of treatment No case should be considered to have had every available treatment that has not received (1) postural treatment administered in the light of modern orthopædic teaching, (2) treatment by light, (3) electrical treatment; and (4) massage

Postural Treatment.

When the attack has been extensive, so that a large number of muscles have been affected, the patient should be kept in bed for a long time, and in cases where the trunk or the lower limbs are extensively affected it is much better to keep the patient in bed for many months Experience has shown that there is much to be gained and little to lose by this measure, provided that the following treatment is adopted So long as acute tenderness persists in the muscles of a limb, that limb should be splinted, great care being taken to prevent the pressure of bandages over the affected muscles This is most important.

In the case of the lower limb, the sole of the foot should be kept at a right angle with the leg, or, when tibialis anticus is the chief consideration, slightly dorsiflexed When tenderness has disappeared, I think the use of rigid splints should at once be abandoned—with the exception of the rectangular splint for the foot, of which more will be said later—and a method of slinging the limb adopted in its place The leg may be slung by bandages from a bar fixed longitudinally over the bed, a padded gutter splint being used to prevent the pressure of the bandages upon the calf muscles If the glutei are affected, the leg is slung just clear of the bed If the psoas is affected and the glutei are not, the leg is raised to a higher level in order to relieve traction upon the psoas, and if the quadriceps are not affected, the knee may, with advantage, be flexed

The rationale of this method is as follows Our object is to assist recovery of tone in those muscles that have partial or temporary disturbance of their innervation The effect of a rigid splint is to prevent recovery of tone In fact, it is known to cause loss of tone even in a muscle that has a normal innervation, and use is made of this knowledge when a splint is applied to a fractured limb By slinging the limb this influence of the splint is to a great extent avoided, and there is no traction on the affected muscles The patient may be encouraged to move the limb at will in such a way as to restore function, these movements—possibly very feeble and scarcely perceptible—being made possible by its suspension on the bandages which absorb its weight It is, indeed, almost as if the limb were floating in water Even before any voluntary movement is possible, the reflex effect of the slight swaying motion frequently produced in the limb by movements of the patient's body help the return of muscular sensibility, which may be functionally suspended, and reflexly tend to promote nutrition and tone. This treatment, if it can be carried out, is much to be preferred to early ambulation with the limb supported by a caliper, because a caliper has the effect of a splint in regard to muscular tone and function

Mention has been made of a support for the foot I use a Jones foot splint, but with a cushioned strap, which passes from behind the heel round dorsal angle of the foot and keeps the heel well home, obviating the need for tight strapping or bandaging around the foot and leg, which is disastrous to the nutrition of the enveloped tissues

The suspension of the upper limb by slinging, when the deltoid is affected, can be beautifully carried out During the stage of acute tenderness, however, if it is possible, the limb is best splinted on a Fairbanks abduction splint This excellent splint keeps the limb in the best possible position, but a common mistake is to pass a bandage or strap round the upper arm, so as to displace the head of the humerus downwards to the lower margin of the glenoid cavity This malposition is sometimes impossible to rectify later on, and produces a permanent functional paresis in the deltoid, even if that muscle should recover a satisfactory innervation and nutrition The limb can be kept in place upon the splint by a bandage round the forearm only, and the splint may be padded under the upper end of the humerus to ensure that the head of that bone is not displaced downwards when the limb is slung A bandage is passed under the arm close to the axilla, so as to pull the head of the humerus upwards The patient is encouraged to use the hands—as in sewing or knitting—because the movements so produced upon the suspended limb, and the functional effect of this activity, are just the influences most desirable for the paretic deltoid, and there is never any chance of stretching its fibres

When the muscles of the back are weakened, the patient should not be allowed to get up until everything has been done to restore their strength as far as possible To avoid spinal deformity, the patient may be kept in the prone position in bed, by means of a pelvic band, with a triangular cushion under the chest Children are very comfortable and happy in this position, and its effect in strengthening the weakened erector spinæ muscles is very satisfactory. Before the patient is allowed up permanently he should be removed from the bed daily for exercises and electrical treatment to ensure that everything has been done to strengthen the erector spinæ muscles preparatory to his assuming the erect position If this measure were thoroughly enforced, I am convinced that many patients would be saved from spinal deformity

Treatment by Light

After placing some hundreds of cases of infantile paralysis on treatment by natural and artificial light, I am now convinced that this form of treatment is of great benefit It seems to me that the improvement in the nutrition of the nervous system of patients undergoing a carefully regulated light treatment is on a par with that noted in the bones of rickety children Just as the rapid increase in the retention of lime salts in the body, following this application of light, causes a corresponding calcification of the bones in rickets, so the nerve centres appear, by the retention of other nutritional factors, to recover from malnutrition Many patients who have suffered recently from an attack of acute anterior poliomyelitis exhibit symptoms of neurasthenia and these symptoms clear up wonderfully under light treatment. The X ray evidence available in the case of the bones is here wanting, but the clinical symptoms are too marked to be disregarded.

In infantile paralysis we may find that many anterior horn cells are completely obliterated. On the other hand, many are temporarily affected, afterwards to recover, as shown in the regeneration of their axons. Therefore there must be many that tremble in the balance between regeneration and degeneration, and it is just here that the effects of light treatment are so useful in turning the balance in favour of recovery. It is partly on account of the neurasthenic after-effect in the more severe cases of acute anterior poliomyelitis that I have so strongly recommended a prolonged treatment in bed. This can easily be undertaken in such a special establishment as the Heritage Craft Schools at Chailey, where the education and treatment of these patients proceeds concurrently and in accordance with the medical aspect of each individual. With well-to-do patients there is of course, no difficulty.

In addition to the general constitutional effect of the irradiation, we must not overlook the direct effect upon the nutrition of the muscles. This effect, which is marked, is I think due to the action of the red rays. I have dealt fully with this matter in a paper[1] read at the International Congress of Radiology in London in 1925. Special lamps fitted with red screens, for the application of intense red light to the affected limbs, are now available.

I would like especially to point out the danger of disappointing results where the treatment is given by those who are unversed in the delicate operation of heliotherapy. This treatment requires care and discrimination. It demands a clinical experience of the complaint with which we are dealing as well as the technical and scientific details involved in the application of heliotherapy, and, above all, a hospital training. The publication of the paper above referred to has, unfortunately, been followed by the exploitation by manufacturers of lamps for the production of red light and ultra-violet light; these are being purchased on all sides by those who administer the treatment in a manner that can only lead to erroneous conclusions.

Bearing this direct effect of the red rays in mind, it will be seen that the treatment of patients by a mercury-vapour lamp alone falls short of the possibilities offered by a more comprehensive application. As far as artificial light is concerned I prefer my own arrangement of a mercury-vapour lamp plus a group of carbon filament lamps fitted with red screens for use when it is desirable to reduce the infra-red radiation in order to render an intense red radiation supportable. So long, however, as the skin shows no signs of overheating I prefer to discard the red screens so that the whole of the rays are absorbed by the patient.

At the Heritage Craft Schools, when patients suffering from infantile paralysis are undergoing special treatment I am particular that the light treatment shall be uninterrupted. In the winter they have artificial light treatment either daily or three times a week, whilst in the summer they have real sun treatment carefully administered when this is possible; when the weather is overcast they have artificial light. There are three hospitals attached to these schools and at each there is a solarium for real sun treatment and a special department for artificial phototherapy. In many cases of infantile paralysis treatment by light has proved a real boon because of its effect in raising the recuperative powers. Prolonged rest in bed plus phototherapy is an important measure that may greatly influence the prognosis; without phototherapy the treatment in bed may produce debility.

In addition to the muscular atrophy, there is another type of malnutrition that calls for local irradiation. Many cases exhibit profound vascular disturbance leading to stagnation of the blood-supply with consequent blueness and subnormal temperature of the limb. These are the patients that suffer most severely from chilblains in the winter months, and irradiation of their limbs with the carbon filament lamp will be found very useful as a remedial and (better still) as a preventive measure; in this case it may be well to discard the red screen so as to obtain the full infra-red radiation. In establishments where the patients are much exposed to the winter air, the affected limb should afterwards be clothed in a loose and light windproof material. Such a covering, over a woollen sleeve mit or stocking, is better than several layers of woollen material, a fact well known to members of polar expeditions.

Electrical Treatment

The electrical treatment of peripheral nerve injuries and diseases is a special and separate branch of electrotherapeutics. Only by the provision of separate and special training for those who undertake it can efficient electrical treatment for anterior poliomyelitis be secured. A search into neurological or electrotherapeutic literature leads to disappointment, but it is in the technique that teaching is most needed.

There are several types of electric current to be mentioned in this connexion. The *diathermy current* is of great use in promoting circulation in limbs that suffer from severe atrophy, but it should be an axiom that this application is unsafe and unjustifiable unless it is given by a qualified medical man who has made a special study of the subject, or by an assistant working under his direct supervision—that is to say, actually in his presence. I am convinced that lay operators may do much insidious damage to the deep tissues—e g., the sealing up of lymphatic channels, or even worse damage—without any sensation informing the patient and without injury to the skin. With this warning I would reiterate the opinion above expressed as to the benefit to be derived from the use of diathermy.

The interrupted *galvanic current* should be employed, by the longitudinal method, for the treatment of muscles that give no response to faradic currents. In most cases rather large button electrodes should be used, and the affected muscles should be picked out for treatment separately, so that the extent to which each muscle is stimulated may be gauged at each treatment.

There is a threefold reason for applying interrupted galvanic current to muscles temporarily isolated from the influence of their motor nerves. After no more than half a dozen closures of the galvanic current, administered as above advised, the blue skin of a chilled atrophic limb covering the muscle will take on the bright red hue that indicates an active arterial circulation. This evidence of vasodilatation in the skin may be taken as an indication of a similar change in the circulation of the muscle beneath it, because the current penetrates this muscle. In addition, there is the physiological effect of counter-irritation. Thus we secure oxidation and nutrition of the sarcomeres which justifies the production of a series of contractions that take place through the concentration of hydrogen-ions at the cathode each time the circuit is closed. At each contraction we are to suppose, on the acceptable teaching of Prof. A. E. Schaffer, the contractile substance passes into the tubules of the sarcous element which dilate for its reception. Thus the elasticity of the skeletal structure is maintained. Without this galvanic stimulation such activity is impossible, the contractile substance remaining outside the tubules in the relaxed muscle-fibres, so that there is grave risk of a loss of contractility in the muscle which may be permanent, so that the subsequent regeneration of the nerve axons is ineffectual.[2]

In place of the interrupted galvanic current condenser discharges may be substituted. These produce less sensory effect and are useful in the treatment of nervous children, but, in my experience, the physiological result of this method is inferior in vasomotor effect

---

[1] British Journal of Radiology, April, 1926.

[2] Reference may here be made to my paper in the Journal of Bone and Joint Surgery, April, 1923.

Great judgment is needed to ensure that the interrupted galvanic treatment of paralysed muscles is not overdone Results are frequently spoiled for this reason Valuable as this treatment may be when properly administered, it is better left alone if there is any fear of maladministration, because a muscle undergoing this treatment is at the mercy of the operator and may be left in a state of extreme fatigue

In certain cases a reversing metronome may be employed so that the poles at the two electrodes are reversed at each interruption In that case the strength of the stimulus is much increased in proportion to the strength of the current The *faradic current* should always be employed when an efficient contraction can be obtained with a strength of current that is not unduly painful, but coils should be used that have a very stout wire in the secondary winding In fact, the wire of the primary and secondary winding should be of equal calibre I strongly advocate the Smart-Bristow coil as being the most satisfactory type It can be used either with a metronome interrupter or as a surging current by employing the iron core, the latter being the most desirable method in most cases It is never desirable to employ a continuous faradic current—i e , a current that does not fall to zero in a rhythmical manner so as to ensure frequent and adequate periods of complete relaxation in the muscle

In addition to the stimulation of the motor point in particular, the current should be so directed that it streams through the greater part of the muscle This will enhance the effect of the treatment It should be remembered that faradic stimulation of the nerve-supply of a muscle produces an effect on its tone and nutrition that cannot be obtained by the voluntary stimulus alone In cases of partial recovery a fair contraction may be obtained, as a rule, by faradism, long before the patient can produce it by voluntary effort Re-education and faradism should therefore proceed concurrently.

Indications for Treatment

Frequently we are faced with the responsibility of deciding whether treatment is likely to lead to a useful result—that is to say, whether we are justified in advising the parents to seek a prolonged course of treatment that must involve considerable expense The difficulty is greatest when the patient is seen for the first time and is suffering from the effects of an attack of anterior poliomyelitis that has occurred perhaps years ago The affected muscles should be carefully tested, not only as to their innervation but also as to the extent to which atrophy has proceeded, and it must be decided whether the recovery of hopeful muscles is likely to be of any real use in view of the hopeless atrophy of others To detail all the considerations that arise in such a case is impossible in a short paper It is certain that many cases formerly considered beyond remedy have exhibited useful recovery since the comprehensive treatment above outlined has been carried out at Chailey and elsewhere

[Dr Levick concluded his address by describing three cases treated at the Heritage Craft Schools]

CASE 1 is a patient now aged 17 The attack of anterior poliomyelitis occurred 15 years ago When treatment began four years ago he *had* absolutely no voluntary response in his right quadriceps, four months later voluntary response began to appear Now there is a useful recovery so that the caliper he had worn is replaced by a short outside iron.

CASE 2 —The patient suffered from the attack about two years ago, and displays the result of postural treatment for the back muscles and treatment by light He was admitted to the Heritage Hospital annexe six months ago He had never been able to sit upright since the attack owing to weakness of his back muscles which were extremely wasted and atonic He was immediately posturised and given light treatment. The result is, as you see, admirable He can already sit upright without curvature, and the muscles are rapidly returning to normal When he came he had acetonuria This has now disappeared under light treatment

CASE 3 —A boy now aged 4 had an attack when aged 1, affecting quadriceps and the tibialis anticus in the right leg He came under treatment eight months ago He could not articulate, could not masticate or feed himself in any way, was dull and unintelligent, and had incontinence of bowels and bladder He weighed 25 lb and showed definite signs of rickets Now he eats nicely, is very cheerful, and is learning to talk. Voluntary response has returned to the quadriceps He weighs 2 st. 5 lb , and is gaining 2 lb per week This patient affords a fine example of the nutritional effect of phototherapy

Lantern slides were shown illustrating Dr Levick's method of slinging limbs affected by paralysis, as well as other means employed in postural treatment

THE CARDIOVASCULAR CHANGES ASSOCIATED WITH RENAL DISEASE

BY PROF HUGH MACLEAN, M.D., D Sc , F R C.P.

IN discussing cardiovascular changes associated with nephritis it is necessary at the outset to refer briefly to the different manifestations of renal disease Within recent years elaborate classifications of nephritis have been introduced, especially by German observers, and claims have sometimes been made to the effect that such classifications permit an exact diagnosis of the nature of the pathological changes in the kidneys from a study of the symptoms. These claims, however, are more theoretical than practical So far, no investigator has ever been able to correlate the clinical signs and symptoms of renal disease with the pathological lesion in the kidneys The reason for this is obvious Whatever the nature of the histological lesion, the effect on kidney function is generally the same, and since the various symptoms associated with renal disease are directly dependent on disturbances of function, it is clear that the clinical condition may differ but little whatever the exact nature of the pathological change that caused the mischief

Broadly speaking, the different forms of nephritis may be classified under three headings: *Acute nephritis, hydræmic nephritis,* and *azotæmic* or *chronic interstitial nephritis* In acute nephritis all the functions of the kidney are more or less thrown out of action Now the chief renal functions from the clinical standpoint are: (1) excretion of fluid, (2) excretion of salts, and (3) excretion of waste products of protein metabolism In acute nephritis we therefore find that fluid and salt are not excreted, with the result that marked œdema is often present, nitrogenous waste products also tend to be retained, and consequently there is an accumulation of these bodies in the blood

In so-called chronic disease the whole of the kidney functions are not usually involved In hydræmic nephritis there is a difficulty in excreting water and salt, but no difficulty whatever in excreting nitrogenous waste substances In chronic interstitial nephritis (azotæmic nephritis), on the other hand, there is generally no material interference with the excretion of water and salts, but the excretion of waste nitrogenous products is markedly diminished In hydræmic nephritis it follows that the most marked symptom is œdema Azotæmic nephritis, on the contrary, is characterised by an accumulation of waste products in the blood and a low concentration of these bodies in the urine Whether the azotæmic condition arises from a primary acute, or subacute attack of nephritis, or whether its cause is to be found in primary changes in the renal blood-vessels, is quite immaterial as far as the signs and symptoms are concerned From a careful study of the previous history of the patient and of the condition present on examination, we perhaps may guess at the nature of the renal lesion, and subsequent histological examination may prove our surmise to have been correct On other occasions we may be surprised to find that a clinical picture which apparently limited the pathological condition to a certain definite histological change proves to be associated with a lesion altogether different from what we expected.

Cardiovascular Changes in Nephritis.

The association of hypertension, and consequent cardiac enlargement, with chronic interstitial nephritis has long been recognised in clinical medicine. Often in chronic disease the systolic blood pressure is found to approach 200 to 250 mm. mercury or more, while the apex beat may be well outside the middle line in the sixth or seventh interspace; along with the high systolic pressure there is a greater or less rise in diastolic pressure. This condition may be accompanied by a thickening of the walls of the peripheral arteries, but it must be remembered that unless this thickening is very marked it is often exceedingly difficult to gauge. The feel of the artery under the finger may vary considerably with the tone of the vessel wall, so that a perfectly normal artery may sometimes give the impression that it is definitely thickened, while at another time the same artery may feel quite soft. Generally speaking, the diastolic pressure is of more importance in hypertension than is the systolic pressure. A patient with a high diastolic pressure, even if the systolic pressure is not excessively high, may be considered to have a worse outlook than another patient with a similar systolic pressure but a much lower diastolic tension. Obviously, the height of the systolic pressure above the diastolic (the pulse pressure) is really dependent on the force of the cardiac contraction, and a high pulse pressure may only mean that the cardiac muscle is acting in a powerful manner.

Though hypertension is a common symptom in chronic interstitial renal disease, it is by no means always present. From time to time cases of chronic nephritis are encountered in which no obvious cardiovascular changes are present. In a patient whom I saw quite recently there was a history of chronic renal disease extending over many years. When first investigated this patient's blood-urea was 160 mg per 100 c cm. and his maximum urea concentration in the urine about 1·2 per cent. Examination of the cardiovascular system showed that the apex beat was in the usual position and the heart appeared to be normal in every way. The systolic blood pressure was 150 mm. of mercury and the diastolic 95 mm. Two years after this examination the patient contracted some infection and shortly afterwards passed into a uræmic state. During this uræmic period the blood-urea was 340 mg per 100 c cm and the urea in the urine was 0·9 per cent. The heart appeared to be quite normal and the blood pressure was almost exactly the same as it was two years before. Thus, a patient who had suffered from chronic nephritis for many years, and who ultimately died from uræmia, showed no evidence of cardiovascular involvement as the result of his disease. I have seen several cases of this kind from time to time. Sometimes, in the terminal stages of chronic nephritis, it happens that the blood pressure may be more or less normal or even subnormal, but this is often due to a failing heart, and is then of the gravest significance. Though it is undoubtedly the rule for chronic nephritis to be accompanied by hypertension, there are many cases in which this is not so. Chronic nephritis may slowly progress to fatal uræmia without any appreciable involvement of the cardiovascular system.

Some Observation on Cardiovascular Changes following Acute Nephritis.

In severe cases of *acute nephritis* marked hypertension with cardiac enlargement may be present. This is usually a temporary feature and the hypertension subsides when the œdema passes over, while the heart gradually returns to its former size. It is unusual to find hypertension in acute nephritis unless œdema is well marked; indeed, a rising blood pressure in the absence of œdema should suggest the suspicion that we are probably dealing with an acute exacerbation superimposed on a chronic condition. In uncomplicated cases the renal lesion often clears up and complete recovery takes place. In other patients, however, the symptoms are more persistent and the condition gradually develops into a chronic lesion. Generally, the renal efficiency goes gradually down, while at the same time the blood pressure tends to rise and the heart enlarges. This is the usual picture, but as already indicated, some of these patients progress to uræmia without any hypertension at any stage of their illness with the exception of the acute phase. In a few others a very extraordinary result is seen. When the course of the disease is followed up for some years it is found that the renal condition, as indicated by functional tests, gradually improves so that in the course of time the kidneys appear to be more or less efficient. In these cases, however, blood pressure changes begin to manifest themselves shortly after the acute stage of nephritis has passed over, with the result that these cardiovascular changes do not tend to improve with the improvement in renal conditions, but the blood pressure continues to get higher and higher, and the heart larger and larger, until ultimately cardiac failure or a cerebral hæmorrhage, or some infection closes the scene. Apparently, therefore, it sometimes happens that chronic hypertension results from acute nephritis, without any manifestation of progressive renal disease being present. Indeed, the healing of the renal lesion seems to be accompanied in these cases by a progressive rise in blood pressure. This observation may explain some of the puzzling cases we sometimes encounter in examining patients with a definite history of having suffered from a former acute nephritis. As far as I know, this aspect of acute nephritis has not hitherto been emphasised in the literature. I hope to go into this matter very fully in a publication which will appear later.

Hypertension in Hydræmic Nephritis.

In true uncomplicated hydræmic nephritis no cardiovascular changes are seen, however severe the œdema may be. The blood pressure is not raised and the heart is not affected. It is not uncommon to find a markedly high blood pressure in cases of *apparent* hydræmic nephritis, but investigation of kidney function invariably shows that in these cases the hydræmic condition is passing into chronic interstitial nephritis. Functional tests always indicate that the kidneys are inefficient, and the hypertension is but a phase of the chronic azotæmic condition. Since hypertension is so frequently associated with œdema in acute nephritis, it might at first be expected that the extreme degree of œdema so often seen in hydræmic nephritis would also be associated with increased blood pressure. Probably the fact that in hydræmic nephritis the œdema is long-continued enables the cardiovascular mechanism to adjust itself to changed conditions. Whatever the reason, it is an undoubted fact that true hydræmic nephritis does not show cardiovascular changes. I have never seen a case of the pure hydræmic type in which the blood pressure was raised when the kidney function of excreting nitrogenous waste products was quite normal. The following are the results of tests carried out on two patients suffering from excessive œdema and ascites, and apparently, as far as the clinical signs indicated, of the hydræmic nephritis type. In No. 1 the blood pressure was raised, while in No. 2 it was normal. The figures given show quite definitely that in No. 1 the hypertension was associated with azotæmic nephritis. The condition was therefore a mixture of the two forms of nephritis.

No 1	No 2.
Much albuminuria	Much albuminuria
Hyaline and granular casts	Hyaline and granular casts.
Blood-urea = 75 mg per 100 c cm.	Blood-urea = 23 mg per 100 c cm
Urea-concentration test—	Urea-concentration test—
1st hour 1·4 per cent	1st hour 2·9 per cent
2nd ,, 1·6 ,,	2nd ,, 3·5 ,,
Blood pressure = 180/125	Blood pressure = 130/85

Primary Hypertension (Hyperpiesia).

Many discussions have been waged round this form of hypertension, and it is often considered to be due to renal involvement. It is quite certain, however, that in many cases of primary hypertension there is no involvement of the renal functions, as far as can be determined by modern renal tests. There may be, and there often is, some albuminuria, but the presence of a little protein in the urine is no criterion, per se, of the presence of renal disease. In my experience, it is not uncommon for the urine to show traces of protein when hypertension is present, even when the kidneys are found to be quite efficient. High blood pressure and a very much enlarged heart with albuminuria are no indication that the cause of this condition is to be found in a primary renal lesion. This form of hypertension apparently begins as a general condition in the vascular system, and the lesion may, or may not, involve the renal vessels. If it does so renal inefficiency soon becomes manifest and the outlook is bad. If the renal system is spared, the prognosis on the whole is decidedly better. Of course, such accidents as cerebral hæmorrhage may occur at any time, but it is noteworthy that many patients go on for a great number of years with hypertension without any cerebral manifestations. In very severe cases cardiac failure may soon bring death, but on the whole the complication most to be feared from the point of view of general prognosis is involvement of the kidneys. In all cases of hypertension it is well to examine the renal function by modern tests. If the renal condition is found to be satisfactory, it may be taken for granted that the outlook is not necessarily bad, but no opinion should *ever be given unless it is certain that the hypertension has existed for some time*. It is my custom to re-examine such patients in about six months after the first examination, if the first examination indicates a satisfactory renal condition, and an examination six months later shows that the kidneys are as efficient as before, then the outlook is much better. Not very infrequently, when the kidneys are examined at an early stage of the hypertension, little or no evidence of renal inefficiency is found, but unfortunately a subsequent examination a few months later may indicate marked renal involvement. When this is the case the outlook is hopeless. On the other hand, if the kidneys do not become involved at a comparatively early stage of the hypertension, they usually escape, or at any rate are not affected to any material extent. Sometimes it is obvious on first seeing the patient that the hypertension must have existed for a considerable time, for evidence of this may be seen in tortuous arteries. In such a case it is certain that the hypertension must have existed for a considerable period, and in these cases very often the renal condition is good. Here we can say at once that, in the absence of accidents, the prognosis is fairly good, provided the hypertension is not excessive and the cardiac condition fairly satisfactory. The following results obtained from two patients with primary hypertension indicate these points:—

No. 1	No. 2
Heart much enlarged	Heart very much enlarged
1st sound booming	1st sound loud and somewhat booming
2nd aortic much accentuated	2nd aortic accentuated
Blood pressure = 195/120	Blood pressure = 210/130
Renal System, First Examination	
Urine contained albumin	Urine contained albumin
Few hyaline casts present	Few hyaline and granular casts
Blood-urea = 25 mg. per 100 c.cm.	Blood urea = 32 mg. per 100 c.cm.
Urea-concentration test—	Urea-concentration test—
1st hour 3·9 per cent. urea	1st hour 2·6 per cent. urea
2nd " 4·1 " "	2nd 3·1 " "
Condition at Second Examination Six Months Afterwards	
Heart condition as before	Heart much enlarged and rate increased. Sounds not so good as before.
Blood pressure = 200/125	
Blood urea = 23 mg. per 100 c.cm.	Blood-urea = 92 mg. per 100 c.cm.
Urea concentration test—	Urea concentration test—
1st hour 3·6 per cent. urea	1st hour 1·3 per cent. urea
2nd " 3·9 " "	2nd " 1·4 " "

In the case of the second patient the first renal examination showed little or no impairment of efficiency, but six months later the picture was quite different. Very marked renal impairment was then present, and a hopeless prognosis was given. The patient died four months later of uræmia and cardiac failure.

In patient No. 1, a medical man, the renal efficiency was quite as good on the second occasion as it was to begin with, and a fairly good prognosis was given. This patient is still alive and apparently enjoys quite good health after four and a half years. The value of renal efficiency tests is well brought out in these cases.

Not infrequently a hopeless renal condition is found to be present on the first examination, and in such a case prognosis is always extremely grave—in fact, the patient generally survives for a few months only. Despite the fact that renal efficiency is found to be unimpaired in many cases of hypertension, it is the opinion of several authorities that all cases of hypertension originate in some sclerosis of the renal arterioles. These observers admit that the renal function may be quite good, even when a very high blood pressure is present, and in order to surmount this difficulty the explanation generally advanced is to the effect that the renal vascular lesion is not sufficiently marked in these cases to interfere with the blood-supply to the glomeruli. This is the view taken by many investigators, especially those of the German school; but it is very difficult to imagine that a renal lesion which is so slight as not to interfere with renal function could possibly produce such marked general cardiovascular disturbances. Often the most severe cardiac involvement accompanied by very excessive hypertension is present in patients whose kidneys are quite efficient. The slight vascular changes found post mortem in the kidneys of such patients are almost certainly the result, and not the cause, of the hypertension. It must be remembered that there is no opportunity to ascertain histological changes in the kidneys until the condition has ended fatally. Under these conditions one would almost expect to find some changes in the renal vessels.

It is interesting to note that even the advocates of a primary renal vascular lesion being the cause of hypertension agree that a few cases are found in which no evidence of vascular changes in the kidneys can be ascertained. It appears to me that this admission strongly supports the view that in hyperpiesis the primary lesion is not in the kidney, but that the disease is a general one with a tendency to involvement of the smaller vessels in any part of the vascular system. It is true that once the condition of hyperpiesis is established the kidneys may become rapidly involved through degenerative changes in the arterioles, but not infrequently the vessels of other organs, such as the spleen and pancreas, may suffer. It is just a chance whether or not the renal vessels do become involved, though there seems to be a greater tendency for the kidney to be attacked than is the case with other organs.

In view of what has already been discussed under acute nephritis, it is possible that some cases of hyperpiesis may originate in a transient temporary lesion of the kidney, but if so, this lesion often clears up and no sign of its presence can be found when the hyperpiesis manifests itself. The question of hypertension is an extremely interesting one on which but little light has yet been thrown, but it appears to be fairly certain that many severe cases of this condition are not essentially associated with any renal lesion.

ULCERS OF THE LESSER CURVATURE OF THE STOMACH

By H. W. Carson, F.R.C.S.

Chronic gastric ulcer as it is seen by the surgeon—that is, the ulcer with a comparatively long history—is confined to a small area of the stomach wall. It occurs at or near the pylorus and along the lesser curvature. It is unknown on the greater curvature, and if it involves the anterior or posterior wall of the body of the stomach it is generally due to extension from the lesser curvature. Ulcers near the pylorus have different symptoms and require different treatment from lesser curvature ulcers, and it is to this latter group that I shall confine my remarks.

There is no generally accepted explanation of the causation of gastric ulcers. There are many theories, and much experimental work has been done, but the puzzle has not been solved. The infection theory, that ulcers arise as the result of some blood-borne infection reaching the stomach from some more or less distant focus, is widely held, and it has had the effect of making the clearing-up of obvious sepsis—e.g., in the teeth, tonsils, or nose—a necessary preliminary for all treatment of indigestion. During the course of the operation, too, the surgeon always looks for coexisting disease in the appendix and gall-bladder and deals with it as part of the operation. The tendency to recurrence after excision of a lesser curve ulcer is also a point in favour of the suggestion that the ulcer is not purely a local happening.

Two Types of Ulcer

The usual type is a sharply cut ulcer with much induration, which has a tendency to penetrate through the stomach wall. It does not, however, perforate into the peritoneal cavity, because it causes a protective thickening of the gastro-hepatic omentum, which seals it off. Later on the base of the ulcer may become adherent to the liver or pancreas, and these organs become eroded in a characteristic manner, the depression in the pancreas being egg-cup shaped—that is, its depth is almost equal to its diameter—while the depression in the liver is spoon shaped—that is, its surface is greater than its depth; occasionally both pancreas and liver are eroded by the same ulcer. The other type of ulcer extends superficially rather than deeply, and tends to involve the posterior surface and sometimes the anterior surface of the stomach. To this the name of saddle ulcer has been given. Both these ulcers may give rise to hour-glass stomach, a complication due to scar-tissue contraction resulting from the healing of the ulcer, and thus hour-glass constriction may exist with an ulcer, either healed or breaking down again—a very important point when it comes to treatment. Ulcers may be multiple, and it is fairly common to find a pyloric ulcer coexisting with an hour-glass stomach.

Ulcers of the lesser curvature occur much more often in men than in women (my own figures are 5 : 1) and are seen by the surgeon, often after a long history, generally during the decade 45–55. The history is rarely less than two years and generally more than five, which contrasts strikingly with the history of cancer of the stomach, in which patients come to the surgeon generally within three months of the onset of the symptoms.

Symptoms

The symptoms of a simple ulcer of the lesser curvature are often so characteristic that it may be possible to make a diagnosis on these alone.

1. *Pain* is the most important symptom, and it is this that brings the patient to his doctor in the great majority of cases. It is situated high up in the epigastric angle and sometimes is even retrosternal. It comes on about one and a half hours after food and is practically never relieved by food. In most cases relief is obtained by belching wind, and all cases are relieved by vomiting. At first the pain is intermittent; indeed, there may be definite intervals of complete freedom from pain—not so long as in duodenal ulcer, but still, lasting for a few weeks. The intervals become shorter, and when the gastro-hepatic omentum is implicated, or when the liver or pancreas become adherent, pain becomes more or less constant. It is at this stage that a typical pain in the back occurs, at about the level of the twelfth dorsal and first lumbar vertebræ. This is most marked when the ulcer has eroded the pancreas, but I have noted it in many cases where only the gastro-hepatic omentum was thickened. It generally means that a real crater ulcer is present. Pain now occurs both by night and day, though in the early stages night pain is unusual, thus differing from duodenal ulcer.

2. The next prominent symptom is *vomiting*. This occurs in about 70 per cent. of cases and is of the irritation type—that is to say, it occurs every day, and perhaps more than once a day, in contrast to the type of vomiting seen in pyloric obstruction. It is small in amount and consists of mucus and saliva.

3. The third most constant symptom is *loss of weight*. This is the rule and has been noted in practically all my cases. It is probably due to many causes, of which semi-starvation resulting from a restricted diet, the constant pain, loss of sleep, and the loss of fluid by vomiting are the chief.

Hæmatemesis is not at all common, but if it does occur, and especially if in large quantities, it is a very serious symptom, as it may mean that a large artery has become exposed in the floor of the ulcer. The appetite remains good, but the patient dare not satisfy his hunger because of the pain which is certain to follow.

Confirming the Diagnosis

The diagnosis is confirmed by two methods of investigation, a chemical examination of the stomach contents before and after a test-meal, and X ray examination after a barium meal. Of these there is no doubt that the X ray examination is by far the more valuable, and, indeed, so variable are the results of the chemical examination from day to day that one is placing less and less reliance upon it. But the X ray examination is of the greatest value, and so accurate has it become that over 90 per cent. of lesser curvature ulcers can be correctly diagnosed. Not only can the exact position of the ulcer be determined, but its degree of fixation, its attachment to the liver, or pancreas, and the presence of such a complication as hour-glass stomach are plainly shown. To know the exact position of the ulcer is most important, because the site of the ulcer may have a direct bearing upon the treatment adopted, since ulcers high up near the œsophagus are not well-adapted for surgical interference. On the other hand, if the ulcer proves to be a large crater ulcer, adherent to a neighbouring viscus, then we know that there is little chance that anything short of a surgical operation will cure it. An interesting point brought out by the X rays is the occasional occurrence of cardiospasm in cases of high lesser curve ulcers, and the œsophageal dilatation may be the cause of the retrosternal pain some of the patients complain of.

Examination of the abdomen does not often give much assistance. The ulcer is so high up under the liver, and so adherent, that it cannot be palpated even by the excellent method of examining while the patient is breathing deeply. Sometimes there is a tender spot in the mid-line, high up in the epigastric angle, and sometimes there is a relative rigidity of the upper rectus abdominis, but it is all rather indefinite. One must rely for a diagnosis on a correct interpretation of the history and symptoms and the confirmatory evidence of the X rays.

Treatment

The whole question of treatment is governed by the belief or disbelief in the implantation of cancer on chronic ulcer in this region. In spite of all that has been written or said on this subject we do not yet know, but many surgeons are convinced that cancer does supervene on chronic gastric ulcers in a proportion of cases. My own belief is that it happens, but that it does not happen very often. The great majority of cases of cancer of the stomach that I see have a short history, about three months on the average, and there is little doubt that in such cases the cancer is a new formation. But the mere fact that one is convinced that an occasional case may occur makes one suspect every case and plan its treatment with this idea constantly in view. It comes to a question of what may be called the direct versus the indirect attack.

By the *direct attack* I mean an operation designed to remove the ulcer, and under this heading one includes excision by knife or cautery, with or without gastro-jejunostomy, or some form of partial gastrectomy, whether it be a sleeve resection, Billroth II, or Polya

By *indirect attack* I understand the adoption of methods designed to promote the healing of the ulcer, and this will include such varied methods as duodenal feeding through the duodenal tube, or the performance of gastro-jejunostomy or of a jejunostomy The supporters of the direct attack have to convince themselves that the operation carries with it a sufficiently low mortality to be justifiable, and that recurrence of the ulcer is a sufficiently remote contingency The supporters of the indirect attack have to convince themselves that their method will cure a high percentage of cases, that the immediate mortality is low, and that recurrence is rare

Direct Attack

Holding as I do the belief that a proportion, though a small one, of chronic ulcers become malignant, I am bound to support the direct attack, but before I suspected the connexion I had abandoned routine gastro-jejunostomy because this operation, which we all used to do in the early days of gastric surgery, did not cure enough of my cases where the ulcer was distant from the pyloric sphincter My first modification was to do a local destruction of the ulcer, either by excision with a knife or burning out with a cautery, but I found a high rate of recurrence. Then I combined excision with gastro-jejunostomy and got better results Then I did sleeve resection on suitable cases and was well satisfied with my results, but could find comparatively few cases suitable for the operation Then I adopted the Billroth II method, but found it better suited for ulcers near the pylorus than for lesser curve ulcers For the last few years I have been doing resection by the Polya method more and more, and I have found the results most satisfactory In chronic ulcer the immediate mortality is about 5 per cent, the convalescence is peculiarly smooth and uneventful, and so far I have not had any ulceration occurring at the stoma suture line If the ulcer is small and I do not feel justified in sacrificing a large extent of healthy stomach, I do an excision and gastro-jejunostomy.

Indirect Attack

I gave up gastro-jejunostomy as a routine because I did not get good enough results in my lesser curve ulcer cases, and in the last few years I have operated on many cases of persistent or recurrent ulceration after gastro-jejunostomy, some even causing perforation I agree that the operation carries with it a very low mortality, perhaps 1 per cent, but its failures are too numerous in spite of many brilliant successes to recommend it as a routine Duodenal feeding and jejunostomy are in the experimental stage. Both are designed with the idea of putting the stomach at rest, though the presence of the tube in the case of duodenal feeding rather militates against this

Several questions have still to be answered, of which two are most important · (1) How long should the artificial feeding be maintained ? and (2) Will the ulcer remain healed ? The answer to the first question depends, of course, on the extent of the ulcer and the fixation of its base It used to be said that 18 months were required to ensure healing, but I feel sure the tendency has been to go on too long At a meeting of the Medical Society of London last January, Mr J. E H Roberts showed a specimen of an ulcer adherent to the pancreas, which had healed in five weeks, and I showed one eroding the pancreas which had healed in 13 weeks after jejunostomy The present method in duodenal feeding through the duodenal tube is to maintain artificial feeding for three weeks only, and 50 per cent of cures are claimed We shall know more about this matter, and also about the permanence of the cure, in a few years' time, but I feel that there may be a future for both these methods

Complications

There are two complications of lesser curvature ulcers which should be mentioned (1) hæmorrhage, and (2) hour-glass stomach

Hæmorrhage is a grave complication and one where the surgeon must keep a very cool head It is difficult to estimate the correct time for intervention, and here a close cooperation with one's medical colleague, valuable at all times in gastric surgery, is absolutely imperative The tendency is to operate, not too soon, but too late, but I do not mean to infer that surgery is the method of choice in hæmorrhage Far from it, indeed, for an operation if it has to be done must necessarily be a severe one, for some form of direct attack is essential, and it will be done necessarily on a patient who is a poor surgical risk At a discussion held at the Royal Society of Medicine a few years ago there was a general agreement that while 4 per cent represents the mortality of gastric hæmorrhage treated medically, the mortality after operation was nearer 40 per cent, due doubtless in many cases to delay I do not, of course, suggest that these cases were all chronic ulcers, nor do I believe that 4 per cent would represent the mortality in hæmorrhage from *chronic ulcer* treated medically. Three steps should be taken in every case of hæmorrhage from a chronic ulcer· (1) estimate the hæmoglobin, (2) group the blood, (3) arrange for a donor for transfusion If the hæmoglobin is reduced to 30 per cent. operation is practically certain to be fatal, even if transfusion is done But transfusion has undoubtedly improved the chances of successful surgical intervention

Hour-glass Stomach —This may arise in the course of a chronic simple lesser curve ulcer. It gives rise to severe symptoms, vomiting and wasting being the most important. I would lay down one rule in the surgical treatment of this condition In no case where active ulceration is going on may any indirect method be adopted If the ulceration is healed, well and good There is a wide choice of methods, nearly all of which will give good results Some form of plastic operation on the isthmus may be used, or the cardiac and pyloric sacs may be anastomosed (this is probably the best), or a gastro-jejunostomy may be done into the cardiac sac, or a gastro jejunostomy into both sacs One word of caution is necessary In many of these cases there is a second ulcer causing pyloric obstruction, and in such a case no purely plastic operation on the stomach is permissible If the ulcer is active, if it is malignant, and in certain cases of healed ulcer, *a partial gastrectomy is the correct procedure*, and in my experience has generally proved technically easy I have done sleeve resection in a few cases with free pylorus, but as I said before, suitable cases are not very common

Summing-up

1 Gastro-jejunostomy is not a curative operation where the pylorus is unaffected

2 Excision by knife or cautery is often followed by recurrence and should not be done

3 Excision with gastro-jejunostomy gives a fair measure of success, but may be more difficult to do, and more trying to the patient than partial gastrectomy It should be confined to small non-adherent ulcers

4 Sleeve resection is a good operation, but is practicable in only a small proportion of cases

5 An ulcer eroding the liver or pancreas should, if possible, be treated by partial gastrectomy

6 Jejunostomy or duodenal feeding may prove to be a valuable method of treating ulcers so high on the lesser curvature that direct attack is technically impossible

---

THE PERMANENT TRACHEOTOMY TUBE

BY SIR STCLAIR THOMSON, M D, F R C P,
F R C S

IT is an interesting observation that tracheotomy, though an established operation of surgery for over 2000 years, is often undertaken with reluctance, is frequently delayed until its execution becomes difficult and even useless, and in its performance is not uncommonly imperfect or unsatisfactory The justification of these criticisms would require more time than can be given, but it is necessary to mention them before discussing, as I propose to do, the equally interesting observation that once a tracheotomy has been performed, and urgent symptoms relieved, many surgeons and laryngologists display an unreasonable and unwarrantable haste in attempting to dispense with the cannula

Objections to a Permanent Tracheotomy Tube

Many reasons are advanced for getting rid of a tracheotomy tube as soon as possible. Perhaps the chief one is that it is not "natural" to inspire the outside air directly into the trachea, instead of having it first warmed, moistened, and filtered by drawing it through the nose As a consequence it is asserted that the cold and dust-laden air will inevitably damage the lower air-passages and the lungs, causing bronchial, pulmonary, and other troubles. Amongst other objections raised against the permanent wearing of a tracheotomy tube are interference with speech, local discomfort, and social disability.

Nasal Respiration.

No one has more regard than I have for the importance and value of nasal respiration. I may be pardoned for justifying this by referring to my own researches (with R T. Hewlett) on the defensive mechanisms of the nose[1] and on micro-organisms in the nasal cavities[2] My observations further confirmed the value of nasal respiration as elucidated by Greville McDonald[3] and others Our conclusions that, under normal conditions, inspired air in its passage through the healthy nose, before it has reached the lungs or even the larynx, is warmed, saturated with moisture, and sterilised, are now universally accepted.

But this nasal respiration, though the physiological and desirable route is not always possible permanently It is particularly important to safeguard it in the growing child and, fortunately, we are able, by attention to adenoids, tonsils, and other conditions, to retain it or restore it before secondary effects to the developing body have resulted from nasal stenosis In the adult, however, absence of an adequate nasal air-way is by no means so important. I agree with the epigram attributed to an American colleague that "man is the only animal that breathes through his mouth, and he is a fool when he does so" Still, as man does not breathe through his mouth willingly—for nasal respiration is instinctive and mouth-breathing is an acquired habit—it need not be counted to him for foolishness Once an individual has grown to man's estate, the onset of nasal stenosis and consequent mouth-breathing does certainly reduce the protection supplied by free and healthy nasal cavities But when symptoms, in the adult, are often attributed to nasal lesions, they are more frequently due to the accompanying sepsis than to mere stenosis

Nasal Respiration in Children and Adults

Nature is full of compensations. The individual who carries on most or all of his respiration through a tracheotomy opening is doomed—so say the enthusiasts of nasal respiration—to suffer and die an early death in consequence If the individual is a child I agree as to this being a possibility above the average The young human is certainly more prone to respiratory catarrh than the adult; his unused nasal and pharyngeal cavities, from want of use, will not develop fully; his larynx, from disuse, will not expand; his defect or loss of voice handicaps his education, and his inability to mix freely with his fellows, in school and in games, is a serious hindrance to his evolution

But in the adult some of these drawbacks do not exist and others are much less urgent The body has attained full growth; education is completed; any voice defects are due to laryngeal or other lesions and not to the presence of the cannula; whilst local discomfort in the neck (i e, a pain, discharge, the need of dressings, frequent cleansing and changing of the tube) is entirely absent in a well-planned tracheotomy. Social disability hardly exists. Except that a patient who has to depend on a tracheotomy tube cannot enter the water or swim, I know of no serious social disadvantage entailed by its presence. I will relate the cases of patients who can cycle, dance, play tennis or golf, indulge in winter sports, get married and beget children, who are what the French call *canulards*—individuals compelled to wear a tracheotomy tube indefinitely. One healthy old lady of 87 whose case is on record,[4] has worn a tube for 70 years; she had seven children and never had bronchitis. In another case the patient died of senile decay at the age of 81, after wearing a tube for over 50 years[5]

Nature of the Operation.

I venture to suggest that, amongst other reasons, the two following may explain why such records are not more plentiful The first is that many tracheotomies are incorrectly performed; the tube is not uncommonly introduced through the first ring of the trachea and the cricoid cartilage, or through the cricoid and crico-thyroid membrane, or even through the latter and through part of the thyroid cartilage. As a consequence there is much catarrh and irritation in the larynx, the soft structures abundant in the subglottic area (and absent in the trachea) are infected; perichondritis may be started, and septic bronchitis is a frequent sequela Another reason is that ill-considered operative measures to dilate a stenosed larynx (so as to cure a *canulard*) not infrequently result in death When a tube has to be worn permanently the tracheotomy should be performed as low as possible in the neck and always below the first three rings. In this situation—with the opening in the trachea just above the upper margin of the sternum—a cannula is easily concealed, does not interfere with the movements of the neck or larynx, does not damage or irritate the larynx, and never sets up perichondritis

There is no excuse for leaving a patient permanently with a high tracheotomy. If the operation is an emergency one, or carried out in haste without proper assistance and surroundings, it is of course, easier to plunge a knife through a prominent cricoid cartilage, or the superficial first ring of the trachea, than it is to make a dissection lower down the neck of the more deeply situated windpipe Indeed, in certain circumstances it may be quite the right procedure to save life But once this is accomplished, and it appears that a tube may have to be worn indefinitely, then a second tracheotomy should be performed lower down in the neck and the higher opening should be allowed to close

In many instances the laryngeal condition calling for a tracheotomy can be removed, or a resulting stenosis of the glottis can be cured, and the tracheotomy tube is then abandoned with safety. Amongst such conditions I need only mention impacted foreign bodies, acute laryngitis, œdema of the larynx, diphtheria, typhoid, syphilis, and tubercle In many cases, however, the laryngeal stenosis is permanent, and attempts to remove it may sometimes fail and entail further damage or complete loss of voice, while in other cases surgical traumatism may only scar the neck, stimulate further stenosis, or encourage recurrence of arrested disease Many methods of overcoming laryngeal stenosis, such as laryngotracheostomy, are tedious, painful, often unsatisfactory, and not free from danger to life The alternative—the permanent wearing of a cannula in a well-executed opening just above the sternum—is, in adults, not incompatible with a long, healthy, and useful life It will often preserve a useful voice while avoiding a mutilating excision of the larynx.

Illustrative Cases

I have not made out anything like a full record of cases in my practice to justify this thesis But I append short notes of some ten typical cases of patients who are permanent *canulards* as a result of a variety of conditions These include (1) complete bilateral laryngeal paralysis, (2) stenosis from surgical trauma, (3) syphilis, (4) lupus, (5) tuberculosis, (6) enchondroma of larynx, and (7) epithelioma of larynx

---

[2] Med Chir Trans, 1895, lxxviii

[3] Respiratory Functions of the Nose, London, 1889.

[4] R Woods Brit Med. Jour, 1925, i, 733

[5] W A. Berridge Ibid., 1912, i, 816

Case 1 —*Complete Bilateral Laryngeal Paralysis* —A girl of 20 was operated on, in the provinces, for a goitre and presented herself at King's College Hospital in March, 1923, with marked stridor, even when at rest, and complete bilateral abductor paralysis A good low tracheotomy was performed under local anæsthesia Her weight, which had *fallen to 104 lb*, has now returned to 123 lb Her voice is good She works hard in a factory The tube is easily concealed by her dress and causes her no disability She has worn it for four years and has never had a day's illness No bronchitis, catarrh, or other trouble can be attributed to it

This case is well worth noting and comparing with the many operative attempts which have been made to correct the laryngeal stenosis caused by bilateral laryngeal paralysis These attempts have rarely, if ever, been successful in the human being As a rule they have entailed long, trying, and painful treatment, leaving the disappointment of a much scarred neck and deterioration or destruction of the voice In not a few cases they have been followed by death

Case 2 *Stenosis from Surgical Trauma* —(After laryngofissure for intrinsic cancer followed by wearing of a tube for eight months and then laryngostomy) A man, aged 47, consulted a colleague abroad for a mammelated growth of the right vocal cord Biopsy revealed an epithelioma Laryngofissure was performed under local anæsthesia on July 8th, 1920, with "destruction of the neoplasm with the thermo-cautery" A tracheotomy tube was left in place for nearly six months The larynx closed up almost completely and laryngostomy was performed on Oct 3rd, 1920, and dilatation with rubber tubes was maintained until the Dec 27th

I saw him for the first time five months later Both vocal cords were fixed, leaving only a much reduced glottic chink There was no evidence of disease The immobility of the cords was presumably due to subglottic cicatricial retraction Under local anæsthesia a low tracheotomy was performed The rings, through which the cannula was introduced, had evidently not been incised in any other operation The relief to the patient has been remarkable He has been able to resume golf, playing two rounds a day His voice is louder and stronger than before the tracheotomy Being low down in his neck the cannula is easily concealed and he declares he would not like to be without it He has now worn it for seven years

Case 3 *Syphilis* —In 1899 I performed tracheotomy on a woman of 34 for stridor and suffocative attacks caused by laryngeal stenosis from syphilis, for which I had been seeing her for two years I saw her 20 years afterward, in 1919, when I found her weighing 154 lb and looking in robust health She reported that she could dance and play tennis, was never subject to bronchitis She had two healthy children, aged 18 and 19

Case 4 *Lupus of Larynx* —A lady, aged 33, had lupus from the age of 5, with prolonged and varied treatment Tracheotomy was done in 1916 on account of urgent laryngeal stenosis The tube has now been worn for 11 years, during which time she has married and has a healthy child aged 9 There has been no appearance of lupus on palate, gums, cheeks, pharynx, or larynx for past four years

When she is sitting still the laryngeal air-way is abundant, so she corks up the tracheotomy cannula at meals She can even walk about with the tube closed, but as she is an enthusiastic dancer, skater, and lawn-tennis player she prefers the superaeration supplied through the opening in her neck Her voice is strong and clear The cords have regenerated and are free and mobile The stenosis is in the aditus ad laryngem, caused by scarring and contraction of the epiglottis and aryepiglottic folds It might be possible to dilate this, but patient declines any effort which would part her from her tracheotomy tube She remembers with horror the increasing dyspnœa she suffered during the year before she would accept my advice of a tracheotomy The tube is so easily concealed by chiffon and gauze that not one of her dancing partners—even, as I have tested, when they were laryngologists—has detected its presence It causes her no social inconvenience, except that she cannot enter a swimming bath! She never gets bronchitis and states that she has fewer colds than most people

Tuberculosis of the Larynx

Case 5 —A woman, aged 42, had tuberculosis in her lungs and larynx for two years before admission to King Edward's Sanatorium, Midhurst, in June, 1923 Her appendix had been removed for tuberculosis There were T B + in sputum, and both lungs were affected. There was ulceration of both cords and the right side of the larynx was fixed from a large, extensive deposit in the right ventricular band and the right arytenoid Under silence and the galvano-cautery, with sanatorium treatment, the larynx was healed in a year (by June, 1924) But the right cord remained fixed, and healing was followed by so much scarring and contraction that the glottic space was *reduced to a chink* She had dyspnœa on the slightest exertion and could not go upstairs. On Oct. 22nd, 1924, a low tracheotomy was performed under local anæsthesia. She has worn her tracheotomy tube for nearly three years She weighs 14 lb more than when she came to the sanatorium four years ago She has had no set-backs, can walk several miles, seldom rests through the day, and gets through a lot of domestic work Her sputum is negative. Her voice is good, but the glottic chink is quite inadequate for ordinary respiration

Case 6 —A woman, aged 32, was admitted to the sanatorium in September, *1911*, with *T B +* in the sputum, disease in the right lung, and a large tuberculous deposit in the interarytenoid region She had a long course of tuberculin and sanatorium treatment, but healing only took place after 18 applications of the galvano-cautery between August, 1912, and May, 1917 The larynx has, since this last date, remained soundly healed, but contraction of the scar tissue in the larynx very gradually took place and, at the end of five years (i e, in October, 1922) a tracheotomy was required

Her pulmonary trouble is quite arrested She can walk for miles and climb stairs, and easily carries on her occupation as mistress of a country post office. It is 16 years since her larynx was healed and she has worn a tracheotomy tube continuously for nearly five years It gives her no inconvenience

Case 7 —A man of 29 was sent to me in January, 1926, for "laryngeal paralysis" For 18 months he had had symptoms and for some weeks his sleep had been fitful, owing to laryngeal stridor, yet his case had not been diagnosed He had tuberculosis with T B + in the sputum The glottis was reduced to a mere chink owing to a grey, irregular, cauliflower infiltration of both vocal cords and a large cauliflower subglottic growth This appeared to spring from the left side, which was quite fixed Tracheotomy was performed under local anæsthesia and he was sent to a sanatorium

When next seen, ten months later (October, 1926), he was free from stridor and had such a wide open glottis that he breathed quite freely when the tube was blocked. The cauliflower growth had disappeared and both vocal cords had completely healed and were intact He could only talk in a whisper and it was seen that this was due to his inability to adduct the cords and close the glottis, owing to partial fixation of the arytenoid joints - This is doubtless caused by deposit and healing of tuberculous deposits in the subglottic areas, as some ulcerating granulations were visible below the posterior half of each cord This remarkable improvement has taken place although *X rays show intense infiltration all over both* lungs with some breaking down in upper and middle zones Tubercle bacilli are still present in sputum His weight is 169 lb and he can walk several miles, but it will still take some time to secure complete arrest of the pulmonary disease Perhaps before that takes place we may abandon his tracheotomy tube But its continuance can do him *no harm and* its adoption has saved his life

Case 8 *Chondroma of the Larynx* —A patient in 1914 began to experience failure of voice Tracheotomy was "contemplated" but not carried out until he had been well treated for a conjectured diagnosis of syphilis Tracheotomy had to be performed "in haste" in 1916 In 1920 Mr E B Waggett diagnosed and removed a chondroma of the cricoid, leaving a tracheotomy tube in situ The growth recurred I saw the patient in consultation in 1923 and Mr Waggett again operated in March of that year The patient has remained well since, speaking with "a very passable voice," able to conduct "without discomfort" his official duties as a consul, and wearing a valved tracheotomy tube[*]

Intrinsic Carcinoma of the Larynx

Case 9 —(Laryngofissure followed in eight months by hemilaryngectomy Tracheotomy tube worn for seven years Active life Strong voice)

A woman aged 41, was hoarse for three years before presenting herself at the early age of 33 with epithelioma invading the entire right vocal cord The diagnosis was confirmed by biopsy. Although the pathologist (A K Gordon) expressed opinion that the growth was highly malignant, it was decided in view of the limitation to cord and the free mobility of the latter, to first attempt a cure by laryngofissure. When this was performed on August 5th 1919 (eight years ago) it was noted that the growth extended close up to the margin posteriorly. Within four months there was a suspicion of recurrence but she did not present herself again until four months later when the right half of the endolarynx was fixed by growth On May 7th, 1920 through a lateral pharyngotomy, the right half of the thyroid and cricoid were removed by Wilfred Trotter and skin flaps folded it in to make a fresh lining to that side of the larynx. But the lumen of the larynx is not sufficiently large for free respiration so she has now worn a tracheotomy tube for seven years. Her voice is loud and strong though rough. She thinks nothing of a walk of six or more miles and during these years has never missed a full day's work in a pottery where she earns a good livelihood She weighs 105 lb never has bronchitis and the tube which is taken out and cleaned every eight or ten weeks causes her no inconvenience. She never has bronchitis

---

[*] E B Waggett Jour of Laryn, 1921 No xli 338 and 1925, No 1, 27, StClair Thomson Jour of Laryng 1925, No 1 1

CASE 10.—(Laryngofissure on one cord 11 years ago Regrowth on opposite cord seven years afterwards. Second laryngofissure. Tracheotomy tube worn for four years Good health useful voice)

A lady aged 46 was hoarse for 18 months before being operated on in August, 1916 for epithelioma invading all the right vocal cord which was sluggish in movement. The diagnosis was confirmed by biopsy She remained free from disease, in excellent health with a voice quite as good as when she presented herself before operation, and was able to gain her livelihood as a companion with a fair amount of reading aloud as part of her duty After seven years of healthy and useful life during which she neither wore a tracheotomy tube nor had other disability she returned with a nodular cauliflower, dimpled growth on anterior half of the left (the opposite) cord For this the patient underwent her second laryngofissure on Dec 6th, 1923.

She has worn a tracheotomy tube permanently since then Nearly four years have passed. In her larynx one sees two cicatricial cords. The right one is quite fixed (the original cord was removed in its entire length) but the left moves fairly well and allows of some voice. The glottic space—although naturally much reduced after a double laryngofissure—is quite adequate for respiration and when the patient is sitting still she corks up the tracheotomy opening and at meals for instance can carry on conversation in a low rough whisper without any embarrassment. But, as the air-way is not sufficient for active life, she can work and walk about with the silver cannula concealed in her neck, still fulfilling her duties as a companion The tube is only taken out for cleansing purposes every three months There is no mucus or discharge around it. She gets no winter cough. She has never had bronchitis

How much healthier, happier, and more useful are these two women than they would have been had the entire larynx been excised! They have suffered no harm and but little inconvenience from wearing a tracheotomy tube for, respectively, seven and four years

---

HOSPITAL COÖRDINATION AT SHEFFIELD.—An advisory committee has just been formed, the object of which is to bring about closer coöperation and coördination among hospitals in an area within 25 miles of Sheffield and to develop their efficiency The scheme includes four hospitals in the city with 1050 beds and eight outside with about 700 beds Autonomy will in no way be affected nor will the functions of any voluntary hospitals committee be interfered with.

THE LATE DR. JAMES M. WILSON—Dr. James Mitchell Wilson late medical officer of health of the East Riding of Yorkshire died at Beverley on May 29th at the age of 83 He was born at Perth and was educated at the Dollar Academy and at the University of Glasgow, where he graduated in 1867. After a period of practice at Chatteris he decided to take up public health work and in 1877 took the D.P.H. at Cambridge. Five years later he proceeded to the M D degree at Glasgow. He held the appointments of medical officer of health for Doncaster Borough and for Rochdale Borough and went to the East Riding in 1901. He was also a past president of the East Yorkshire branch of the British Medical Association. Among his publications was a Note-book for Inspectors under the Dairies and Cowshed Orders. He leaves a widow and three sons.

GENERAL MEDICAL COUNCIL.

SUMMER SESSION, 1927.

(*Concluded from p 1202*)

APART from the hearing of charges against professional conduct reported in our last issue, a few matters of more general interest came before the Council.

An Incorrect Entry in the Medical Register.

The Council held an inquiry into the circumstances under which the name of John Richard Brinkley had come to be entered in the Register, and whether or not the entry was incorrect. Mr. Brinkley was a resident of the United States who lived at Milford, Kansas and qualified at the Eclectic School there. Wishing to qualify for the English Register, he had gone to Italy, where reciprocity with this country existed, and had passed the examinations which entitled him to the degree of M.D. Pavia in 1925. He had not studied in Italy, but his American qualification had been accepted. Subsequently, however, the registration authorities at Rome had cancelled his Pavia degree on the grounds that they were not satisfied that the standard required by the Eclectic School was adequate to entitle a graduate of that body to practise in Italy. Therefore, said the Council's solicitor, the entry was incorrect and could not be allowed to stand, but he had no intention whatever of suggesting that Mr Brinkley had acted in any way that was not completely above board. The Council decided to erase the entry, finding that it had been made upon information tendered in good faith, but now ascertained to be incorrect. They directed that the registration fee be returned to Mr. Brinkley.

Covering Uncertified Persons Practising as Midwives: Alteration in Warning Notice.

On the recommendation of the Executive Committee the Council decided to amend the Warning Notice regarding association with uncertified persons practising as midwives to read as follows:—

7 Whereas it has been made to appear to the Council that certain registered medical practitioners have from time to time, by their countenance or assistance or by issuing certificates notifications or other documents of a kindred character enabled uncertified persons to attend women in childbirth otherwise than under the direction and personal supervision of a duly qualified medical practitioner contrary to law; and whereas such conduct is in the opinion of the Council discreditable to the profession of medicine and calculated to defeat the purpose of the Statutes made in the public interest for the protection of mothers and infants, notice is hereby given that any registered practitioner who is proved to have so offended will be liable to have his name erased from the Medical Register

Committees and Other Business.

The Council directed the Registrar of the Dental Board to restore to the Dentists Register the name of Samuel Robertson Crosbie on fulfilment of the prescribed requirements

The English Branch Council, which met on Wednesday, appointed Mr Robert Milne, F.R C.S., an assistant examiner in surgery to the Apothecaries' Society of London for a period of five years.

The Chairman of the Finance Committee, Sir Holburt Waring reported a surplus for the year 1926 of £5267 12*s* 1*d*. The total number of registrations was 1947, as against 2569 in 1925 and 2796 in 1924.

The Education Committee have completed the draft of their report on the progress made throughout the country towards the readjustment of the medical curriculum in accordance with the resolutions of the Council adopted on May 26th, 1922. They hope to present the completed report to the Council at the November session.

The Council learned with regret the decision of Dr. J. T. Mackay to resign from his appointment as chairman of the Education Committee.

The Chairman of the Examination Committee, Sir Norman Walker, reported that the number of candidates for examination fell in 1926 to 2273, a figure only slightly higher than that for 1913 No report would be issued on the working of the simultaneous pass in anatomy and physiology until the Committee had further information

Mr Norman C King was unanimously re-elected Registrar to the Council

MEDICINE AND THE LAW

Expert Evidence and the Length of Trials

Some months ago Mr Justice Tomlin proposed to make a rule that in future the number of expert witnesses to be heard in any case before him should be limited to two from either side He was trying a claim made by a colliery company against the Swansea Corporation, it being alleged that the defendant body in filling one of its reservoirs would flood and damage coal-mines belonging to the plaintiff company The hearing, which began before last Christmas, actually occupied 60 days, and judgment has just been delivered After finding for the defendants and explaining his reasons, the learned judge drew attention afresh to the increase in late years of cases involving expert evidence, the greater length of such cases, and the growing elaboration of their preparation What he described as the "overloading" of the case placed the parties with the lesser resources at a grave disadvantage, as well as delaying the course of general business in the courts In every case of that kind, observed his lordship, there were generally many irreducible and stubborn facts upon which agreement between experts should be possible He regarded the expert advisers of the court, whether legal or scientific, as being under a special duty to the court to limit in every possible way the contentious matters of fact to be dealt with at the hearing He thought that all concerned in litigation of this class must in future, in the preparation of their cases, address their minds more closely to the restriction of the area of dispute

The hint will not be lost upon medical and scientific witnesses, though it must be remembered that rules of practice appropriate to hearings in the Chancery Division have no necessary application to trials elsewhere Cases about reservoirs and coal-mines raise questions of geological and engineering facts on which experts may be able to reach some large common measure of agreement in advance of the actual hearing in court Medical questions such as arise in litigation under the Lunacy Act or in criminal trials cannot so easily be reduced to simple facts and figures Personal liberty or professional reputation may be at stake, and it may be inevitable that every fact and inference should be keenly contested Nevertheless, medical witnesses, particularly in accident or workmen's compensation, will always earn the gratitude of the court if they narrow the issues of fact as much as possible and take pains to exhibit matters of agreement as well as matters of dispute Nothing gives so much strength and independence to an expert witness's opinions as a readiness to admit a point which cannot reasonably be controverted

If Mr Justice Tomlin's observations were universally adopted and extended, they would have the effect of converting the expert witness, who at present is employed and paid by either plaintiff or defendant for partisan purposes, into a quasi-judicial officer competent to formulate the issues in the litigation and encouraged to concentrate upon obtaining the maximum of agreement between the two sides In other words, he would become an assessor of the court, or even a referee Judges have considerable powers at present of appointing and employing expert assessors, it is sometimes remarked that these powers are too little employed The court is also fully competent to conduct its proceedings in such a manner as to avoid a case being unnecessarily protracted In the Swansea Corporation case not all the blame must be put upon the scientific expert witnesses, time could have been saved by the legal experts also.

Alleged Negligence in Removal of Tonsils

In a recent action in the Ulster King's Bench Division before a special jury, a father claimed £1500 damages for personal injuries to his daughter, aged 6, on the ground of negligence in carrying out an operation at the Benn Hospital last November The defendant was Dr I A Davidson, a member of the surgical staff of the Benn Hospital, and also of the Ulster Hospital for Women and Children After evidence for the defence had been given by the defendant himself, Mr James A Craig, M R C S, Dr William Dickey, who had administered the anæsthetic, and Mr W M Killen, senior surgeon at the Benn Hospital, a verdict was given in favour of Dr Davidson, who was defended throughout by the London and Counties Medical Protection Society

The plaintiff's claim was that, as the result of the operation for the removal of adenoids and tonsils, his little daughter was unable to take solid food, could not drink in the ordinary way, and developed a nasal intonation in her voice at times From the evidence it appeared that the adenoids and the left tonsil were cleanly removed, but the right tonsil was found to be adherent, in the attempt to remove the latter the uvula was cut off Dr Davidson stated that the operation of removing adenoids and tonsils was one which he had himself performed some 12,000 times and that on this occasion he followed the same procedure and took the same precautions as on other occasions He said the removal of the uvula was an accident which had occurred to him only twice in his career and might occur to the best surgeons in the world He claimed that he had given his best skill and attention to the case In cross-examination he said that he did not know until next morning that the uvula had been removed, and could even now do no more than conjecture the actual moment at which the accident occurred Negative evidence as to the value of the uvula was given by other witnesses, questions were also asked as to the practice of telling or not telling the parents forthwith when such an accident had occurred From the legal point of view there are certain accidents in which negligence is *prima facie* assumed, in the legal phrase *res ipsa loquitur*, the facts speak for themselves This case was not one of these, and, as the jury found that Dr Davidson had exercised reasonable skill and care in the operation, judgment was entered in his favour

VIENNA.

(From our own Correspondent)

The Action of Hypnotics

Prof P Pick recently addressed the Vienna Medical Society on the subject of hypnotics Although, he said, the narcosis produced by inhalation is very similar to that which results from hypnotic drugs, the seat of action is different in the two cases Inhalation generally paralyses first the sensory portion of the cortex, whereas the action of the hypnotics is first directed towards the motor areas and those governing the ocular, labyrinthine and proprioceptive reflexes Inhalation can, of course, be stopped or controlled at any moment, whereas the narcosis induced by hypnotic drugs only disappears gradually as the drug is disintegrated or eliminated By experiments on animals in which the cerebral cortex and corpus striatum has been removed, it has been shown that most of the hypnotics—e g , alcohol, paraldehyde, chloral, urethane, veronal, and luminal—are active in decorticated animals, morphine and scopolamine also cause sleep in thalamic animals

The point of action of most hypnotics is the brain-stem, but the condition of the cortex is, of course, of great importance, and cortical irritation will prevent sleep unless it is controlled—e.g., by bromides or (experimentally) by severing the connexion between the cortex and brain-stem. Calcium salts excite the cortex and thus interrupt the sleep produced by magnesium, but they have no effect on the decorticated animal. Prof. Pick divides hypnotics into two groups, cortical and thalamic. The first includes alcohol, bromide, paraldehyde, and chloral, whilst derivatives of urea, such as veronal and luminal, belong to the second, together with isopral and chloretone. Morphine and scopolamine work in both ways. The most active hypnotics, he argues, are those which combine the effects of the two groups, their cooperation being termed synergism. It has been shown that combinations such as luminal and scopolamine, or chloretone and paraldehyde, are very effective. Even better results are obtained when urethane and medinal is combined with theophyllin, which facilitates penetration of the tissues.

In the discussion following Prof. Pick's lecture, Dr. Dattner pointed out that the physician should distinguish between disturbance before sleep has begun, disturbance of the sleep itself, and disturbance of the sleeper. The first is often due to mental overwork, to caffeine or nicotine, or to emotional causes. The habit of premature awakening so often seen in aged or neurotic people can be combated by improving the circulation, thus promoting better oxygenation of the tissues. A radical change of diet is often very useful, and it is especially desirable to cut down the supply of the exciting substance calcium.

Restriction of the Number of Medical Students.

The two professors of anatomy in the University of Vienna point out that the number of students applying to them for instruction is far in excess of the number which can be taught in the institutes; in the present summer term there have been no less than 600 applicants, of whom only 148 are Austrians. As little dissection is done during this term it has been possible to give instruction to them all, but difficulties will arise in the winter, for there are not enough subjects for dissection, and the professors suggest that the number of first-year students should be restricted so as to allow those taking the course to dissect all parts of the body at least once. It is only possible to get from the hospitals those bodies which are not claimed by friends, and with the decrease of patients at hospitals and the increase of pious burial societies these unclaimed bodies are getting very scarce. At present the two Viennese institutes of anatomy have only a small stock, and the professors suggest that no foreigners should share in the teaching facilities until a place has been found in the schools for every Austrian. The Senate and the public receive this proposal with mixed feelings. The general opinion is that it would be a mistake, over so small a matter, to endanger the standing of Vienna as the chief university in Eastern Europe. It must be possible, it is felt, to ensure by law that there shall be an adequate supply of subjects for the dissecting room. A large section of the public suspects that the proposal to select a limited number of students is really aimed at the Polish and Hungarian Jews, who flock to Vienna because feeling in their own countries is strongly anti-Semitic.

Medical Graduation in Austria.

During the winter term the three Austrian universities—Vienna, Graz, and Innsbruck—have conferred the degree of M.D. on 427 candidates, entitling them to practise medicine. Of these, 252 were conferred at Vienna, 115 at Graz, and 60 at Innsbruck, and it is interesting to note that the percentage of foreigners was 65 at Graz, 40 at Vienna, and 30 at Innsbruck; 7 came from Egypt, 1 from the United States, 74 from Bulgaria, 7 from Italy, 30 from Poland, 31 from Roumania, 54 from Yugoslavia, and 5 from other countries.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Celebration of Two Centenaries.

THE French medical profession has been celebrating two centenaries. It is 100 years since the death of Pinel and the birth of Vulpian and the two events have fittingly been commemorated together, for these two men represent two different epochs. "With Pinel," wrote Prof. E. C. Achard, "there disappeared a medicine which seems to us antiquated—a medicine of mere observation, ignorant of true scientific interpretation because it knew hardly anything of pathological anatomy, of physiology, or of precise ætiology, a medicine devoted to verbal dissertations, to nomenclature, and to classification. With Vulpian arose a generation which was already instructed in morbid anatomy and perfected it by histological investigation, which invoked new knowledge of physiology to interpret pathological processes, and which began to emphasise the rôle of microbic organisms as a cause of disease."

The Prevention of Tuberculosis.

At the recent national congress on tuberculosis, which was held at Lyons, Dr. Leon Bernard and Dr. Poix, of Paris, reported on the care of the pre-tuberculous child, dealing with preventoriums and the placing of children in families, as suggested and carried out by Grancher. The plan is to entrust the children to doctors in the country who choose homes for them among the peasants and give them the necessary care and supervision. On the same basis is the scheme for boarding out the babies of tuberculous parents, of which such excellent results are reported. Whereas the mortality among those who remain in their infected homes is about 80 per cent., the percentage death-rate of those who are isolated from birth is less than six, whilst that of infants already exposed to infection but transferred to better surroundings is only about eight.

Intracardiac Remedies.

In pulmonary diseases drugs given by the mouth are often inactive, those passed into the trachea are largely coughed out, whilst with intravenous injections the place of entry is always so far from the lung that the effect of a massive dose is lost by dilution before the remedy gets to the seat of the disease. On these grounds Cherechewski, Florentin, and Lesbouyries suggest—though it seems a little risky—that medicaments should be injected straight into the right side of the heart, whence they would be carried directly into the pulmonary circulation. Their experimental research on the dog has proved, they say, that the procedure is not dangerous, and they consider that it opens a way to the better treatment of pulmonary tubercle in man and of the same and other infections in animals. They are pursuing their experiments with a view to applying the results tentatively to human beings.

Yellow Fever.

The Académie de Médecine has received a report of the cases of yellow fever observed in French West Africa between July, 1926, and February, 1927. The epidemic began in the British colonies of the Gold Coast and Nigeria. The neighbouring districts of Dahomey and Haute Volta were well protected, and only two cases were reported from each of them; but in Senegal, where the white population lives in close contact with the natives, the number of victims was much greater. The fact that the cases were scattered over an immense area made sanitary measures very difficult. Nevertheless, thanks to immediate and rigorous precautions, the number of severe cases was relatively small (34 cases with 29 deaths). Noguchi's vaccine and serum were used with advantage, whilst efforts to prevent the disease from spreading included the isolation of patients, the destruction of stegomyia in infected houses and those adjoining, the discovery and clearance of the breeding-places of larvæ, and the supervision of travellers

Synthalin

Chabanier and Lebert have recently described their observations on the treatment of diabetes mellitus with synthalin They have investigated 27 cases of which 19 were severe, and they have come to the conclusion that the remedy is not by itself sufficient for treatment where the condition of the patient is serious In the dosage needed to get the same results as with insulin the drug generally upsets the mucous membrane of the stomach or intestine, so that its administration has to be stopped Even where the disturbance is not so great as this the synthalin has a bad effect on the appetite, sometimes abolishing it altogether, at the same time the patient gets thinner and shows an asthenia which is in contrast to the well-being which insulin produces The suggestion that alternate courses of the two drugs should be given does not seem to have much to recommend it Synthalin has a good effect on patients with mild diabetes, but here also it is commonly found that it cannot be given at all continuously In its present form, therefore the remedy is apparently not of much practical value.

Diphtheria.

The mortality from diphtheria during the outbreaks last January was exceptionally high, ranging from 12-18 per cent in the non-malignant cases to 50 per cent in the malignant forms This mortality was generally due to associated and secondary affections, especially streptococcal and pneumococcal Empyema, pneumococcal arthritis, and broncho-pneumonia were particularly noticeable Influenza was likewise an important contributory cause of the mortality

A method of nasal vaccination against the disease has recently been tested by Lesné and others in a series of 124 children, the Ramon anatoxin being employed Immunity was judged by the Schick test The nasal method appeared satisfactory, but the investigators do not recommend it as a general substitute for subcutaneous vaccination

Intraspinal Analgesia

A wave of opinion adverse to the intraspinal method of producing analgesia seems to be developing in France, a number of deaths and failures having been recently reported The method is being advised for occasional use only

Several cases of iodism following injection of lipiodol into the bronchi have recently been reported from different hospitals at Paris

A physician in the south of France received, during the process of opening a tube of small-pox vaccine, a droplet in the left eye Ensuing keratitis, iritis, and iridocyclitis became aggravated, and enucleation of the affected eye was unavoidable This case illustrates the precautions which should be observed in manipulating small-pox vaccine

The International Commission on Occupational Diseases, which was formed in 1906, has just been reorganised Some 17 countries are represented The secretary, Dr L Carozzi, may be addressed at Geneva, Switzerland

BERLIN.

(FROM OUR OWN CORRESPONDENT)

Congress of the German Surgical Association

IN a paper at the recent surgical congress Dr Rost (Mannheim) said that 10 per cent of deaths after operation were due to heart troubles He also drew attention to the danger of operating on patients who have recently had influenza, respiratory complications being very common in those cases In 1926, he said, pulmonary embolism increased considerably in frequency, for some reason unknown There seemed to be no reliable means of preventing or curing post-operative pneumonia, but pneumococcal serum and inhalations of CO_2 proved valuable sometimes As regards preparation for operation it was very important to attend to the bowel, but no strong purgative should be given

Prof F Sauerbruch (Munich) discussed the origin and surgical treatment of bronchiectasis, which was not, he said, a sequel to bronchitis or broncho pneumonia, as was generally supposed, but was due to congenital cystic dilatation of the bronchi Eighty per cent of the lesions in bronchiectasis affected the left lower lobe, this being due to the position of the Cuvier's duct, which hindered the development of the left lung Bronchiectasis and bronchial cysts might exist a long time, not causing any symptoms until infection occurred Cure was possible by radical removal of the left lower lobe

Prof V Schmieden (Frankfort) said that in pancreatitis the infection may come from the gall-bladder, from the canal of Wirsung, from the veins, lymphatic vessels, or from a penetrating duodenal ulcer, or it may follow embolism of the pancreatic artery Infection from the gall-bladder is the cause in two thirds of the cases, and in cholelithiasis, according to Prof Schmieden, the gall-bladder should always be removed, cholecystotomy being insufficient because it does not reduce the pressure in the gall-bladder Apart from necrosis, which sometimes occurs rather early, the dangers connected with pancreatitis are hæmorrhage and acute peritonitis with septicæmia A correct diagnosis, Prof Schmieden said, had been made in 40 per cent of 1510 cases described in the literature Early operation was nearly always indicated In cases where the condition at first produced only an œdema of the pancreas, 76 per cent of the patients were cured by operation Delay was only justifiable when there was severe collapse or where the surgeon, consulted rather late, found a fairly normal pulse-rate and might decide to wait until an abscess was formed Where the diagnosis was not quite certain and there were severe abdominal symptoms suggesting pancreatitis, it was undesirable to wait until the full symptoms had developed The general mortality of cases in which operation was done was 50 per cent The operation consisted of wide incision of the capsule with drainage, sometimes the gland itself was also incised

Prof Paul Clairmont (Zurich) stated that in a series of 1298 cases of appendicitis conveyed to the Zurich Surgical Clinic on behalf of practitioners, the diagnosis was erroneous in 20 per cent This statement must not be looked upon as a reproach to the general practitioner, on the contrary, it was satisfactory to find that medical men were growing more and more accustomed to have every suspicious case investigated by a surgeon In 85 of the cases a correct diagnosis was subsequently made at the clinic, whilst in 6 per cent of those operated on it was found that the disease was not appendicitis Prof F Konig (Wurzburg) said that in doubtful cases the surgeon ought to operate because otherwise practitioners would tend to wait before sending up urgent cases.

Avertin

Reporting on the new anæsthetic, E 107, or avertin,[1] Dr F Eichholz (Elberfeld) said that it is quickly absorbed, that there are no complaints after narcosis, and that it has no undesirable action on the circulation and the blood pressure Disturbance of respiration occurs only when double the narcotic dose is administered Dr Butzengeier (Elberfeld) said that to obtain narcosis 0 1 g avertin per kg of the patient's weight should be given by enema 20 minutes before operation The patient, as a rule, *begins to sleep after a few* minutes If he does not an additional dose, one-quarter of the first, may be administered, but the total amount given should never exceed 0 15 g per kg The patient sleeps for three or four hours and does not vomit Persons with disease of the colon are not suitable subjects A few drops of ether may be given, if considered necessary, to accelerate the narcosis Prof Nordmann (Berlin) offered a warning against producing full narcosis with the compound alone ; in 40 per cent of his 250 cases a few drops of ether had to be given to aid its action Prof F Sauerbruch had observed three cases in which avertin caused erosion of the colon with fatal results Prof E Unger (Berlin) recommended that the drug should be dissolved in a mucinous fluid In about 70 per cent of cases, he said, the narcosis was successful, but eight patients had symptoms of severe asphyxia Dr. Melzer (Konigsberg) reported that in 100 cases there was no irritation of the colon , on the other hand, there were in this series 18 with cardiac disturbance, four deaths occurring among them The main drawback to the method is that the dose cannot be regulated during the narcosis, so that the fate of the patient depends on the amount originally given

X Rays and Childbearing

In the *Archiv fur Gynakologie* Dr Werner has published an article dealing with the remote influence of X rays on the offspring of women who have been irradiated The effect of treating excessive hæmorrhage or fibroids by X rays is, he says, to render first abortions more frequent Whereas the usual number of abortions is one to every five normal births, the ratio where X rays have been applied is one abortion to every two births In a series of 22 women pregnant after Rontgen treatment there were 45 pregnancies, of which only 27 lasted to term Five of the infants died very young and of the 22 that survived one suffered from congenital stenosis of the trachea, one from congenital cardiac disease, one from rickets, one from tuberculosis, and one from general debility Two-thirds of them had a weight considerably below the normal It follows, according to Dr Werner, that X rays have a very unfavourable action on the offspring and that this influence will certainly become more marked in the generation to come The treatment of pregnant women with X rays is, he says, still more undesirable, many infants being born as idiots or microcephalics.

A committee presided over by Prof Schilling and Prof A Magnus-Levy has been investigating 2820 cases of pernicious or Addisonian anæmia The features of the disease, it is stated, have not altered, but three times more cases were notified in 1924 than in 1915 The suggestion is made that the war, the blockade, and economic distress have contributed to this increase.

The price of German scientific books is sometimes regarded as excessively high abroad According to the *American Review for Biology* this idea is mistaken The average prices for a page in a scientific book may be expressed (in cents) as in England 1 28, in the United States 1 12, in Germany 1 09, in France 0 35, and in other countries 1 51 The low price of French books is attributed to the state of the French currency

Public Health Services.

MENTAL HOSPITAL REPORTS

The *City of London Mental Hospital* at Stone, Dartford, has a remarkably clean bill of health to report for 1926 There was but one case of tuberculosis, and that a latent one, and no dysentery or other epidemic or zymotic disease For 600 mental patients this is a record that must be hard to beat Thirty patients died during the year, a death-rate of 4 2 Post-mortem examinations were held in 12 instances The recovery-rate was 55 8 per cent These figures do not include the 38 voluntary boarders admitted during the year There is a diminution in the number of rate-aided patients, and 70 per cent of admissions belonged to the " private " class An operating theatre, dental surgery, X ray room, and pathological laboratory have been equipped and brought into use Ultra-violet ray therapy is a regular method of treatment, and a section has been equipped for the malarial treatment of cases of general paralysis More wireless sets have been installed, and the entertainments for the patients are many and varied The farm has produced all the mutton, pork, milk, eggs, poultry, and vegetables needed by the institution Research on the variability of certain constituents of the blood in mental disease is being carried on in the laboratory The visiting commissioner was well satisfied with what he saw, and remarks " So much has been done to bring this hospital into line with modern ideas that I cannot but congratulate Dr Robinson and the committee on all that has been completed " There are open door and club wards, and parole is allowed beyond the estate to 73 patients and within the grounds to 152 more A sister tutor has been appointed, and four nurses obtained their M P A certificate during the year, while three more passed the preliminary examination

The *Glasgow Royal Asylum*, which publishes its 113th annual report for the year 1926, is another institution where the proportion of voluntary inmates is steadily increasing Of the 148 patients admitted during the year, 78 were uncertified The average number resident was 533, which constitutes a record , the death-rate was 8 8 per cent and the recovery-rate 34 6 per cent There was a small outbreak of scarlet fever and one case of typhus Rapid progress is being made with the construction of an operating theatre and dental room, and a central kitchen and a refuse destructor are being built Two general paralytics have been treated by malaria, and one has begun to show improvement Over 400 attendances were recorded at the psychiatric out-patient clinic of the Western Infirmary The occupational therapy department has organised a scheme of consideration of each patient as an individual, so that work can be adapted to each Women who are very ill do simple raffia, woolwork, needlework, or card weaving More convalescent cases do batik and vety colour work, and there is a small room for a noisy or disturbed patient who works best alone In the central hall there are a series of tables for all kinds of crafts, and parole patients are free to come and go as they like On the other side of the hall is a room for cooperative men patients, doing cane and basket work brass repousse work, and chip carving The second room is a carpenter's shop, and for more difficult cases there is wool-winding, sand-papering, polishing, picture pasting and brushwork, among other occupations The instructress presents an interesting special report on this work 298 patients saw the dentist during the year , very few refused treatment

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 28TH, 1927.

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 266 (last week 313) , scarlet fever, 1478 , diphtheria 845 , enteric fever, 38 , pneumonia, 941 , puerperal fever, 32 , puerperal pyrexia, 107 , cerebro-spinal fever, 7 , acute poliomyelitis, 9 , encephalitis lethargica, 28 , dysentery, 9 , ophthalmia neonatorum, 114

Cases of small-pox were notified from the counties of London 1 (Hackney), Derby 8, Durham 112, Lancaster 23, Northumberland 8, Nottingham 2, Stafford 1 (Bilston), Yorks North Riding, 7, West Riding 39, Glamorgan 1 (Gelligaer), Monmouth 31

Deaths —In the aggregate of great towns, including London, there were *2 deaths* from small-pox, 1 (0) from enteric fever, 42 (2) from measles, 11 (5) from scarlet fever, 22 (4) from whooping-cough, 26 (9) from diphtheria, 47 (9) from diarrhœa and enteritis under 2 years, and 43 (7) from influenza The figures in parentheses are those for London itself Of the two deaths from small-pox one was registered from the metropolitan borough of Hackney, the other from Hendon (Middlesex), referred to a death which occurred during the week ended May 11th

Correspondence.

"Audi alteram partem"

THE TOTAL ECLIPSE OF JUNE 29TH

To the Editor of The Lancet

Sir,—May I be allowed to point out the danger of *not* seeing the eclipse? The question of the dark adaption of the eye before the total phase seems very largely to have been ignored in the instructions given to the public, yet it is a matter that will make all the difference between seeing the corona well and seeing it badly—possibly, even, between seeing it and not seeing it.

In the days when visual observations of the corona were all-important the blindfolding of the observers five or ten minutes before totality was a recognised part of official programmes. On June 29th this precaution, or its equivalent, will be enormously more important than usual, for three reasons:—

1. Since the moon's shadow on this occasion is very narrow (about 15 miles broad) the brightness of the surrounding sky will be great and will largely "swamp" the coronal light.
2. Since the sun is at an extremely low altitude the light of the corona will be considerably diminished by atmospheric absorption.
3. Since totality only lasts about 20 seconds the eye will not have time to become dark-adapted. In fact, except for its bright lowest layers, the corona will be very difficult to see.

I do not suggest blindfolding. Few would do it, and those that did would not know when totality had started; some would remove the bandage too soon and undo all the good of blindfolding, others would remove it too late and miss part or all of those few seconds of totality. But I do suggest the desirability of putting on some dark, opaque mask—say, lined velvet—in which there are two eyeholes occupied by deeply tinted screens. The mask should tie tightly behind the head and so fit the face that no light can get in round the sides.

The screens must be the darkest that will still allow the sun just to be visible. Their density of tint will depend on the condition of the sky at the place and time in question. The simplest device is a number of strips of fogged photographic film of different densities. The darkest that still shows the sun should be used, and held firmly against the front of the mask. In that way one will be able to watch the partial phase and still achieve dark-adaption of the eye when the mask is slipped off at totality.

I know a lot has been written about the dangers to the eye of ultra-violet light and the inadequate protection of fogged films, but at the coming eclipse ultra-violet light will not enter into the question. At such a low altitude of the sun it will (unfortunately for astronomers) be almost entirely absorbed by the atmosphere.

But if the ultra-violet light during the partial phase can be ignored, the visible violet and blue light during totality should be taken account of. Since "scattering" of light in the air is inversely proportional to a high power of the wave-length, the visible light of the sky is mainly violet and blue. Hence we may hope to diminish the "swamping" of the corona by sky-light by watching totality through a simple yellow-tinted photographic light filter—one, I suggest, of which the "exposure factor" does not exceed 2.

I am, Sir, yours faithfully,
R. L. Waterfield.

The Royal Astronomical Society, Burlington House,
June 4th, 1927.

THE *Z* NOTION IN PSYCHOLOGY

To the Editor of The Lancet

Sir,—The review in last week's issue of The Lancet of Prof. McDougall's "Outline of Abnormal Psychology" prompts me to offer a hint to psychologists and to physicians. Apparently the view is spreading that a man is a conglomeration of cells, each of which has a personality that finds its self-expression in self-sacrifice to promote the continuance of the man. So far so good. Let the student of conduct take a step further and regard man as fundamentally and principally a chance unit in the conglomeration of creatures, animal and vegetable, that find their self-realisation in sacrificing themselves to ensure the continuance of the fundamental arch-creature that consists of all protoplasm that ever was, is, and will be; a creature that may be visualised as a thin, hollow sphere of some 8000 miles in diameter and may be symbolised in speech and writing by the letter Z. The theory, supported by nothing but by man's egoism, that the human race is a "whole" in the scheme of things has ever been a philosophical failure; it has made ethics, not only to the Greeks, foolishness, and psychology a castle in the air. The *Z* notion, carefully followed to its logical conclusions (each step checked by painstaking observation) can explain why man does as he does. It provides an entertaining field for philosophical speculation on an unhackneyed path, and—what to me matters most—it is the key to a treatment of the folks who have epilepsy that does more good than harm.

I am, Sir, yours faithfully,
Alan McDougall.

EXACERBATION OF CHOLECYSTITIS AFTER INJECTION OF SODIUM-TETRIODO PHENOLPHTHALEIN

To the Editor of The Lancet

Sir,—The following case seems to me to be of interest in showing a local disturbance due to injection of this dye in a case of cholecystitis. The patient, aged 59, housewife, was admitted to Charing Cross Hospital under Mr. N. C. Lake on March 30th last with symptoms pointing to a recent attack of cholecystitis. The injection of 30 c.cm. of the dye for cholecystography was immediately followed by a rise in temperature and lighting up of cholecystitis. Cholecystectomy was performed on the following day and all these symptoms rapidly disappeared. I do not think this complication in cholecystography has been reported before.

I am, Sir, yours faithfully,
E. A. Crook,
Surgical Registrar, Charing Cross Hospital.
June 3rd, 1927.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Whitsuntide Recess

The House of Commons adjourned for the Whitsuntide recess on Thursday, June 2nd. The House will meet again on Monday, June 13th.

Early Shop Closing and the Health of Young Girls

Dr. Marion Phillips and Mrs. Adamson gave evidence on May 31st on behalf of the Standing Joint Committee of Industrial Women's Organisations before the Departmental Committee appointed by the Home Secretary to inquire into the working of the Shops (Early Closing) Acts. They stated that in their opinion the best system of regulating shop hours would be by a general closing order which would require all shops to close at 7 P.M. on four days, 12 on one day, and 8 on one day. From their information the day on which the later closing day was most convenient is Friday; this was especially the case in textile areas where there were a large number of women who were both wage-earners and housewives. They had noted, however, that in a large number of districts the coöperative stores already closed at earlier hours than those without causing any difficulties, and the witnesses thought that there should be a power given to a local authority to make orders for closing at 6 o'clock. Such orders should not be made until full inquiry had taken place, and in making the inquiry the opinion of the shop assistants should be taken The inquiries the witnesses had made in regard to confectioners' shops showed that there was no real demand for the present later hours which prevailed It had been pointed out to them that very often the girls employed were extremely young and suffered physically from the long hours These shop assistants changed very frequently, probably because the work was found too heavy Instances had been given of sickness and general debility among the girls in these shops One case had been given where the girls usually stayed in bed on Sunday because of their exhaustion after the long Saturday hours The witnesses held that a 48-hour week should be established for the workers, in addition to regulating the closing hours

The Committee adjourned until June 15th

HOUSE OF COMMONS.

Wednesday, June 1st

Artificial Light Treatment for Children

Sir Robert Thomas asked the Minister of Health what medical facilities existed in North Wales for the free treatment of children by ultra-violet light, in view of the value of this method of treating rickets, surgical tuberculosis, and other complaints to which children are liable —Major Barnston replied My right hon friend is informed that the Flintshire and Denbighshire County Councils and the Wrexham Town Council have made arrangements for the provision of artificial light treatment for children at the Orthopædic Hospital at Gobowen, and that other county councils in North Wales occasionally send children to this hospital for treatment Provision has been made by the Welsh National Memorial Association at the Wrexham Dispensary for artificial light treatment for children suffering from surgical tuberculosis, and it is also proposed to instal the necessary apparatus for this treatment at the North Wales Sanatorium, Denbigh

Local Authorities and Provision of Playing Fields

Mr Campbell asked the Minister of Health whether, in view of the importance of securing for the nation playing fields throughout Great Britain, he could take any steps to encourage local authorities to use their powers to acquire, lay out, and maintain land for the purposes of games and recreation.—Major Barnston replied My right hon friend can only repeat what has already been said in reply to similar questions He is willing to consider sympathetically applications for sanction to loans for playing fields from local authorities, and a good deal has, in fact, been expended in recent years in the acquisition and laying out of land, though heavy rates and the present need for economy have prevented local authorities in some instances from making full use of their powers My right hon friend has also made a practice of urging local authorities to reserve land for open spaces and playing fields in their town-planning schemes

Pensioner's Refusal to Undergo Operation

Mr Harmsworth asked the Minister of Pensions whether, having regard to the recommendation for operation at Queen Mary's Hospital, Roehampton, recently made in the case of a pensioner, he was still satisfied with the decision of the Ministry in November last year that the degree of disablement arising from the man's pensionable disability had been reduced from 30 per cent to 20 per cent , and whether the present degree of disablement was still at the latter figure —Major Tyron replied I find that this man has refused to undergo the operation recommended and has, therefore, been discharged from hospital as no other treatment is likely to be of benefit to him. In these circumstances I am not in a position to reconsider the assessment of the case.

Standardisation of Vaccines and Serums

Mr Groves asked the Minister of Health whether he had issued any regulations dealing with the standardisation of vaccines and serums , and, if so, whether such regulations had been published for sale —Mr Chamberlain replied Draft regulations under the Therapeutic Substances Act, 1925, were published and placed on sale last April Substantive regulations have now been made after consideration of representations from the trade and other interests concerned and will come into operation on August 6th next, except those relating to labelling, which will not come into operation till Feb 6th, 1928 These regulations will be laid before Parliament and will be available immediately after the Whitsun recess

Thursday, June 2nd.

Purity of Condensed Milk

Major Ainsworth asked the Minister of Health whether any standard test of purity and quality was applied to the importations of condensed milk into this country, especially from Switzerland , and, if so, what it was and how it was carried out —Mr Chamberlain replied Samples of condensed milk are examined by the Government chemist and by public analysts to verify that it complies with the standard of composition laid down in the Public Health (Condensed Milk) Regulations, and is otherwise free from adulteration The tests applied are matters for the discretion of the officers concerned, no standard tests being prescribed I am not aware that any special attention is given to imports from Switzerland

The Powers of the General Medical Council

Mr Macquisten asked the Minister of Health whether, in view of the modern developments in the science and art of healing, he would cause to be appointed a Royal Commission to inquire into the operation of the Medical Acts of 1858, with a view to the alteration of the law, especially with reference to the powers and privileges of the General Medical Council —Mr Chamberlain replied: No, Sir I do not think that modern developments in therapeutics necessitate any revision of the powers and duties of the General Medical Council, and my right hon friend the Lord President of the Council shares my view

Persons Insured under National Health Insurance

Mr Herbert Williams asked the Minister of Health the number of males and females, respectively, who were insured under the National Health Insurance Act in England and Wales at the end of 1926, and the increase since the end of 1925 —Mr Chamberlain replied The approximate number of insured persons in England and Wales at the end of 1926 (inclusive of persons over 70 years of age who have ceased to pay contributions) was males 9,837,000, females 4,658,000, the increases since the end of 1925 being 251,000 and 68,000 respectively

Mr Herbert Williams asked the Secretary of State for Scotland the number of males and females, respectively, insured under the National Health Insurance Act in Scotland at the end of 1926, and the increases, as compared with 1925 —Sir J Gilmour replied At the end of 1926 there were 1,144,000 males and 571,000 females insured in Scotland under the National Health Insurance Act. These figures represent an increase of 28,000 and a decrease of 1000 respectively on the corresponding figures for 1925

Health of the Troops at Shanghai

Lieut -Commander Kenworthy asked the Secretary of State for War what steps were being taken in the interests of the health and comfort of the troops at Shanghai during the coming hot season , and whether he had considered sending the battalions in turn to Wei-hai-wei during the hot weather —Sir L Worthington-Evans replied Everything possible is being done for the comfort of the troops, and the necessary precautions have been taken to guard against outbreaks of those diseases which are liable to occur during the hot weather A convalescent camp is being formed at Wei-hai-wei

Cholera Epidemic in Bombay Presidency

Mr Morgan Jones asked the Under Secretary of State for India whether he would give information as to the extent of the cholera epidemic in Bombay Presidency , and whether the epidemic was still spreading —Earl Winterton replied The latest official figures of attacks and deaths from cholera in the four affected districts in the Bombay Presidency relate to the week ended April 16th, and are as follows —

	Attacks	Deaths
Belgaum District	1182*	575*
Dharwar „	872†	401†
Bijapur „	743‡	256‡
Kanara „	21	20

* Including 541 attacks and 249 deaths, † including 666 attacks and 316 deaths, ‡ including 104 attacks and 56 deaths which occurred previously but were reported during the week According to press reports the totals in the four affected districts in the two following weeks were —

	Attacks	Deaths
Week ended April 23rd	1401	607
„ „ , 30th	1092	461

The latest official information received contains no figures, but indicates that the conditions continue to improve

Women Police Doctors

Mr Day asked the Home Secretary whether there had been any women police doctors appointed in the metropolitan police area —Sir William Joynson-Hicks replied No women have been appointed to these posts

Medical News.

University of Cambridge —At a Congregation held on June 4th the following degrees were conferred —

M D—C H C Dalton, E H H Granger, and L E H Whitby

M B—H V Dicks and H V Coverdale

M B, B Chir—R K Debenham R L Lancaster, R D Milford, J H Randall, and R L Smith

University of London —At recent examinations for the degrees of M B, B S the following candidates were successful —

With Honours—Gilbert Cleary Babington (*a*), Max Barer (*a*, *b*, University Medal), Ernest Arthur Freeman (*d*), George Richard Nicol Henry (*a*), Winifred Annie Ladds (*b*, *c*) Florence Louis (*a*), James Meadowcroft Turner (*d*), Edwin Charles Warner (*b*), Hubert Lyon Campbell Wood (*a*, *c*) (*a*) Distinguished in Medicine (*b*) Distinguished in Pathology (*d*) Distinguished in Surgery (*c*) Distinguished in Midwifery

Ordinary Degree—Charles Everett Heyworth Anson, Cécile Helen Denise Asher, Arthur Leslie Banks, John Templeton Barr, Raymond Edward Barrett, Douglas Elliott Barton, Arthur David Belilios, Joan Helen Blackledge, Douglas Arthur Blount Eleanor Dorothea Blunt, Hilda Maud Price Bond, Derek Gordon Bown, Denis Anderton Brigg, Muriel Brighton, Margaret Hughes Brown, Helen Marion Browne, Helen Rosa Betty Buck Thomas Saville Cochrane Alexander Cohen, Mary Cecilia Emsley Constantine, Edgar Stuart Curtiss, Frederick James Darbyshire, Gwilym Ivor Davies, Tom Emrys Davies, John Dean, Arthur Edgar de Chazal, Jean Marguerite Dollar, Margaret Relach Dunlop, Malcolm Herbert Cecil Dyson, John Evans, Frederick Mortimer Maurice Eyton Jones Dora Janet Fox, Alfred Edward Fraser Smith, Joel Gabe, Bernard Mario Cole Gilsenan, Arkyl Staveley Gough, William Pickup Greenwood, Charles Herbert Hampshire, Kathleen Hoyes, Henry Frederick Hiscocks, Janet Ireland Hoare Joan Houseman Eric Graham Howe, Aust Hilton Jackson, Margaret Evelyn Ledger, William Leslie Albert Henry Levers, Marian Lones, Joan Lydia Lush, Joyce McConnell, Alexander Cameron MacLeod, Gurdit Singh Malik Charles Wallace Marshall Isaac Maonde, John Wright Nankivell, Helen Edith Maud Newman, Joan Nixon, Marjorie Ethel Parfitt, Stephen Mary Power, Marion Ravell, John Herbert Owen Roberts, Llywelyn Roberts, Wemyss Cameron Robinson, Enid Helen Rockstro, Sidney Thomas Seccombe, Moses Sendak, Joseph Silverstone, Kenneth Shirley Smith, George Ernest Frederick Sutton, Frederick William la Bois Kathleen Edith Tresilian Maeve Whelen, Elizabeth May Whishaw John Stanley Whitton, Harry Keith Williams, Bernard Hugh Hahnemann Wooderson, Eric Wornum

The following candidates were successful in the undermentioned parts of the examination :—

Group I—Marjorie Flowers Brierley, Douglas Arthur Dewhirst, Phyllis Mary Edgar, Libero Fatti, Abraham Golombek Charles Bertram Huss Caroline Mary Kingsmill, Frank Edward Kingston, Richard Alban Vaughan Lewys Lloyd Isabella Louise Hamilton Livingstone, William Edward Lock Helen Elizabeth Mayfield Bertha Inez Meyer Ethel Elizabeth Mary Ogilvie, Evelyn Doris Owen, George Edward Basham Payne, Margaret Eveline Peaker Kudatelagé Richard Theobald Peiris Edwin Seymour Phillips, Robert Lionel Quilliam, Eric Walter Skipper, John Robert Colquhoun Spicer, Victoria Winifred Symonds, Olive Mary Thomas, Frank Sheerman Thornton, Winifred Mary Turner Joan Beatrice Walker Richard Fowler Ward, Ronald Morgan Williams, Harry David Wyse

Group II—George Thomas Allerton, Chandumal Asanand Amesur, Vernon FitzClarence Anderson, Charles Glynne Bowen, Frank William Bradley Philip John Lauriston Capon, John Adye Cholmeley, Doris Beatrice Clay, Roy Reiach Fells Percy Hebden Flockton, James Rocheid Forrest Krishnalal Tribhovandas Gajjar, Dorothy Godden, Colin Hugh Harper Theodore Henry Hobbes, Kenneth Harry Lachlan, Malcolm Langley Maloy, William Drew Nicol Nathoobhai Dayalji Patel, Gangadhar Martand Phadke Brian Fitzgerald Russell, Charles Francis Joy Smith William Robert Colquhoun Spicer, Kathleen Mary Stuart Harris, Olive Fredrica Sydenham, Edward Cowper Tamplin Fauset Welsh John George Weston, Charles Louis Worthington, Elsie Bodley Wright

University of Edinburgh —On July 20th, during the British Medical Association's visit to Edinburgh, the degree of Doctor of Laws will be conferred on Lord Dawson of Penn, Prof Archibald Donald (Manchester), Dr C E Douglas (Cupar), Sir William Hale-White (London), Mr R G Hogarth (President of the Association), Dr William Hunter (London), Prof T H Milroy (Belfast), Sir Berkeley Moynihan, P R C S Eng, Sir John Parsons (London), Sir Humphry Rolleston (Cambridge), Dr G F Still (London), Mr Wilfred Trotter (London), Sir Almroth Wright (London), Prof. Vittorio Ascoli (Rome), Prof Jules Bordet (Brussels), Prof Harvey Cushing (Harvard), Prof C L Dana (Cornell), Prof Knud Faber (Copenhagen), Prof J van der Hoeve (Leyden), Prof Otto Meyerhof (Berlin), Prof Otto Naegeli (Zürich), Prof W S Thayer (Johns Hopkins), and Dr Theodore Tuffier (Paris)

Royal College of Physicians of Edinburgh —The Dr Alexander Black lecture for 1927 will be delivered by Dr C E Douglas in the hall of the College on Wednesday, *June 15th, at 5 P M* *The subject will be the Family Doctor* as Specialist

Biochemical Society —The next meeting of this society will be held in the Biochemical Department, The Museum, Oxford, to-day, Saturday, June 11th, at 3 P M

Institution of Heating and Ventilating Engineers —The summer meetings of this Institution will be held at Bournemouth from June 20th to 22nd Particulars may be had from the secretary, 12, Russell sq, London, W C 1.

Australian and New Zealand Medical Association in England —The summer dinner of this Association will be held on June 17th at the Piccadilly Hotel Sir John Bland-Sutton will be the official guest Mr Joseph Cunning will be in the chair Medical visitors are invited

National Conference on Maternity and Child Welfare —This conference is to be held in the House of the British Medical Association, Tavistock square, London, W C 1, from July 5th to 8th, under the presidency of Mr Neville Chamberlain, Minister of Health The programme may be obtained from the hon secretary, at 117, Piccadilly, London, W 1

Joint Tuberculosis Council —Sir Henry Gauvain has arranged to hold a post-graduate course on Non pulmonary Tuberculosis at Lord Mayor Treloar Cripples' Hospital and College, Alton Hants, from Monday, June 27th, to Saturday, July 2nd The class is limited to ten members and there will be no fee Particulars may be had from the hon secretary, Post-Graduate Courses, The Larches, Farnham Royal, Bucks

Indian Medical Service Dinner —The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 15th, at 7 15 for 7 30 P M Major-General R W S Lyons will take the chair Tickets and all particulars may be obtained from the joint hon sec, Col J J Pratt, I M S (ret), 18, Nevern Mansions, Warwick-road, London, S W 5

Nursing Awards —The decoration of the Royal Red Cross, Second Class, has been conferred upon Miss Emily de la Hoyde, matron, and Miss Catherine Annie Waugh, nursing sister, both of the Indian Temporary Nursing Service, in recognition of the special devotion and competency displayed by them in their nursing duties with the British Forces in Iraq

The late Dr E L Cambie —The death is announced of Dr Edward Loftus Cambie, on May 28th, at his residence at Templemore, Co Tipperary Educated at the Royal College of Surgeons and at the University of Dublin, Dr Cambie took the qualifying diploma of the Irish Colleges in 1892 At first he practised in *London*, but afterwards settled at Portsmouth, where he worked for 21 years Not long ago he returned to Ireland Dr Cambie leaves a widow and one son

Prizes at London Medical Schools —On Tuesday, June 21st, in the Governors' Hall, the Duke of Connaught will distribute the prizes won at St. Thomas's Hospital Medical School On his *arrival at 3 P M he will* unveil a tablet on which are inscribed the names of those of St. Thomas's Hospital who fell in the late war

The President of the Board of Education, Lord Eustace Percy, on Wednesday, June 29th, at 3 P M, will distribute the prizes at the London Hospital Medical College and Dental School in the College Library

Compulsory Removal —*Proceedings* were taken at Birmingham last week against a young woman who had been certified at the Birmingham Dispensary as suffering from tuberculosis in an infectious stage and who had failed either to take proper precautions against spreading the disease or to accept hospital treatment She shared a bed with a female lodger and had refused to make other arrangements in spite of an offer by the Health Department to lend her a single bed Adjourning the case, the stipendiary magistrate said if she did not comply with the requirement to occupy another bed he would order her removal to a sanatorium

The late Dr H T Wright —After some 12 years of practice at Foleshill, Dr Herbert Trouncer Wright has died at Northampton at the age of 58 He was a Scotsman and qualified with the Scottish triple diploma in 1897 For some years he acted as medical officer of health and public vaccinator for the No 2 district of Alston in Cumberland, then he went to Derby and finally he settled in Foleshill, first as assistant to Dr John Orton, and afterwards in practice by himself Dr Wright was twice married and leaves two children

Medical Diary.

Notes, Comments, and Abstracts.

ON ESTIMATING THE VALUE OF REMEDIES IN PULMONARY TUBERCULOSIS

By F R Walters, M D , M R C P Lond ,
PRESIDENT OF THE SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS

The following remarks are intended to help those who are trying to assess the value of remedies in pulmonary tuberculosis, including so-called " consumption cures " Laymen commonly regard this as a simple matter , but those better acquainted with the disease know well the difficulties and complexity of the problem In testing a remedy we must have fairly definite groups of cases, and use the proposed remedy in a definite and fairly uniform way To arrive at reliable conclusions we need a similar group of cases as a standard of comparison So long as we are dealing with symptomatic remedies this is comparatively easy to arrange, but in seeking a more comprehensive remedy it is far otherwise Hence the long list of such drugs and preparations, beginning with creosote and hypophosphites, ending with the Spahlinger remedies and sanocrysin Some of these have been discredited after a period of great popularity , concerning others medical opinion is much divided , while yet others are still on trial

Analysis of Cases

Our cases should be analysed in a way corresponding with all the more important factors in prognosis , what we have to do is to find out how far the remedy will affect the prognosis

Stage, grade, and complications —One of the earliest methods of appraising the value of treatment in this disease which has stood the test of time was based on the nature and extent of the local lesions (stage), to which was added by others the degree of constitutional disturbance (grade), and the presence or absence of serious complications All the more useful classifications are based upon these principles A classification which is comparable with the chief ones employed in America and the continent, and which comprises and defines these factors, was devised by the Society of Superintendents of Tuberculosis Institutions[1] and adopted by some other kindred societies This classification (or one like it) is essential for our purpose

Type of local disease —Another important point is to decide whether the lesions present are mainly fibroid, mainly exudative (caseation, &c), or mixed The decision is not always easy, but is worth attempting Where there is doubt the case should be classed as mixed in type The distribution of the lesions is also important Well-localised foci are more favourable than scattered tubercle

Activity of the disease —Active disease may be inferred where there are progressive lesions in the chest, or constitutional disturbance, especially febrility or raised pulse-rate Slight febrility is important in this connexion and cannot be detected by the usual methods of thermometry[2] Menstrual fluctuations of temperature in women add considerably to the difficulty of the problem Temperatures are affected by rest and exercise, so that Inman's classification into (1) resting febrile, (2) resting afebrile, ambulant febrile, (3) ambulant afebrile, is useful in gauging progress Tubercle bacilli in the sputum are not an infallible sign of activity They may be present for years without constitutional disturbance or evidence of spread in the lesions

Rate of progress of the disease —Since cases differ greatly in the time occupied in arriving at a similar stage, it is useful to divide them into slow, medium, and rapid This can be done if we can fix the date of appearance of the earliest symptoms attributable to tuberculosis of the lungs Some symptoms—such as hæmoptysis—arise also from other quite unconnected causes I think the best rule would be to regard the symptoms as due to tubercle if there is no other probable cause discoverable, and if there is unmistakable evidence of tuberculosis later on Quite commonly we find evidence of a series of breakdowns of tuberculous nature separated by healthy intervals There may also be a history of tuberculous signs or symptoms in some other part of the body If so, this should be noted, with the date

Mode of onset —We should distinguish the mode of onset—whether insidious, or following immediately after pleurisy, pneumonia or a chest injury, or an acute illness of another kind The illness which caused the breakdown in health may modify the course of the disease

Mixed infection —The presence of other pathogenic organisms in the sputum should also be noted, periodical analyses being made Some remedies which are useful in pulmonary tuberculosis (such as creosote) probably act mainly (or entirely) on associated infections

Natural resistance —Pulmonary tubercle is the resultant of three groups of factors the original infection, the natural resistance, and the conditions of life generally Amongst the latter we can eliminate the cases due to *faulty hygiene* by noting the progress made during an observation month under better conditions The chief point concerning the original infection is to decide whether *massive infection* was likely This may be inferred where there has been close association with a patient suffering from advanced disease and known to have neglected the usual precautions as regards sputum Where both of these causes (faulty hygiene and massive infection) seem to have been absent, and yet the disease has made rapid progress, we may infer feeble resistance Most of our present population have a high resistance to tubercle, since most are infected, but only a minority fall ill with the disease , but after acute illnesses, childbirth, and serious accidents, resistance to tubercle is probably temporarily reduced

The effect of *repeated infections* is still sub judice In my opinion small doses may actually protect, while repeated *large doses of infection at short intervals will almost certainly* reduce the resistance It is not, I think, safe to assume that resistance is low because of a *family history* of tuberculosis alone, as other factors are concerned besides inheritance It is a mistake to regard the disease as mainly due to infection Lack of resistance, temporary or permanent, together with the conditions of life, have much more to do with it In proportion as a community becomes immunised against tubercle, so does the relative importance of causes other than infection increase

Age and sex —The resistance to tubercle is notably dependent upon age and sex In early childhood resistance has not yet been established Later on comes a more favourable period , but with the advent of puberty in girls, and possibly also in boys, the constitution is decidedly less resistant to the disease In women menstruation and childbirth are times of danger, which may help to light up an attack

Conditions of Life

Three sets of factors have to be remembered under this heading *climate and situation*, the *house and quarters*, *personal hygiene and habits* Under the first heading would be included the usual climatic factors which affect health, and the position of the home or institution—whether rural or urban, high up or low lying, dry or damp, sheltered or windswept Under the second heading would fall ventilation, cleanliness, dryness, and state of repair so far as affecting health The third heading would comprise all relevant matters of personal hygiene, food-supply, personal habits, occupation, rest and exercise, and observance or otherwise of sanatorium rules, especially the regulation of the day's happenings according to an accurate temperature record If is not safe to draw conclusions about a general remedy in tuberculosis without taking account of such factors Irregular meals, or shut bedroom windows, or an injudicious excursion will often have more noticeable effect on the health of such a patient than most drugs, even such as are of undoubted value

The Remedy

Mode of employment —Having ensured uniformity in the trial group and control, and in the conditions of life generally, we must be equally definite in the manner of using the remedy The difference of opinion concerning the value of tuberculin is a good example of the confusion which arises through neglect of this precaution Apart from the numerous varieties of tuberculin, there are many ways of administration, differing in dosage, intervals, criteria for choice of these, and conditions under which the remedy is given The most important difference is between the methods of cumulative and non-cumulative dosage In the former method doses are increased as rapidly as constitutional disturbance will permit, another dose being given before the effects of the previous one have worn off, with the result that the sensitiveness of the body to the remedy is eventually abolished In the other method the doses are increased much more slowly, at longer intervals, and a second dose is not given until the effect of the first has subsided, the sensitiveness of the body towards the remedy being maintained or even increased Both of these methods cannot be correct , yet they have not usually been distinguished in the published reports

Adequate time of treatment —Adequate periods of treatment are necessary, both in the controls and in the test cases Under Alpine climatic treatment many cases are recommended to spend two winters and a summer in the Alps , and it would be illogical to condemn the treatment because such a patient did not recover in two months Under ordinary hygienic treatment, lasting results cannot be expected in less than three months in early (first stage) afebrile cases, yet sanatorium treatment is often condemned because patients with well-marked fever or with second or third stage lesions do not get well in three months, such cases need far more prolonged treatment, or the equivalent at home, to secure lasting benefit In every case, whatever the remedy adopted, it should be continued until there is a reasonable probability of the maximum benefit having been attained

---

[2] See S Vere Pearson the Temperature as a Guide to the Treatment and Prognosis of Phthisis, The Lancet, Sept 8th, 1909 , F R Walters Loc cit , p 10, et seq

How the remedy acts—To obtain evidence of permanent value we must know not only that the remedy is useful, but how it acts and under what circumstances The same remedy is not necessarily the best for every stage of the disease, since the hindrances to recovery will not be the same throughout, and the damage done by prolonged illness complicates the matter in the later stages In an early stage the defence is mainly by a modification of the inflammatory process—the formation of granulomata Later on the natural production of antitoxins comes into prominence, and the removal of caseous and other damaged tissues Consequently remedies which increase the amount of circulating toxin—even temporarily—must be used with the greatest caution in patients with extensive lesions or toxæmia

Pulmonary tuberculosis has far-reaching effects on many parts of the body, in well-marked cases there is a steady drain on the immunising machinery, on the organs of nutrition, digestion, and circulation which support it, and on the excretory organs which deal with the products of metabolism in the affected tissues Attack and defence are often very nearly balanced, so that a little extra help may turn the scale For instance, a remedy which restored the appetite and so improved nutrition, or one which ensured refreshing sleep when there was harassing cough, might do immense good, and this is the justification of symptomatic treatment Yet such remedies could not be regarded as "cures" for consumption

No reliable *bactericidal* drug has so far been discovered Many antiseptics kill the bacillus in cultures, but do not reach it in lethal doses in the body without damaging the latter Salts of gold and copper appear to be the most promising Some remedies are known which hinder the growth of the bacillus According to Gräfin von Linden, methylene-blue has such an action in experimented animals Destruction of the bacillus in all but the earliest stages involves katabolism of caseous and other damaged tissues and liberation of toxins

Many remedies are known which *stimulate the immunising organs*, and so act indirectly on tuberculous tissues These remedies fall naturally into two groups, specific and non-specific, of which the former act in very minute doses Prominent examples of the former group are tuberculin and its allies, of the latter group, sanocrysin and other gold salts, copper salts, and cantharidin Probably every member of these two groups causes hyperæmia of the affected tissues Possibly large doses are destructive, while smaller ones promote fibrosis Creosote, guaiacol, and camphor are also stated to promote fibrosis of the tuberculous foci Remedies given to promote leucocytosis and chemotaxis have proved to be disappointing Various balsams were tried for this purpose Cinnamic acid (introduced by Landerer) damages the blood after three days Camphor is stated to have a chemotactic action

Active immunisation with *living bacilli*, in imitation of vaccination against small-pox, has been attempted by Friedmann, Möller, Calmette, and others, but is probably not free from danger

Passive immunisation (as in diphtheria) has been aimed at by a number of investigators, but does not appear to have been satisfactory There is probably some antagonism between active and passive immunisation, as the presence of some circulating toxin appears to be necessary to cause a formation of antitoxins

Biochemical immunisation is quite conceivable, but has not yet been effected, as we know too little about the biochemical difference between those who suffer from infection and those who do not Hygienic remedies, such as an open-air life, occupations promoting the flushing of every part of the lung with pure air, and plenty of suitable food, are still the most efficacious remedies known for protecting the body against tuberculosis Whether vitamins play a part in the defence has not yet been determined We are still doubtful as to the precise mode of action of even so well-established a remedy as cod-liver oil The French method of remineralisation appears to rest upon an insecure foundation Lime salts do not promote healing in tuberculous foci, they merely infiltrate them as they do all unirritating worn out tissues

Surgical methods such as artificial pneumothorax ensure local rest and reduce the absorption of toxins They are, therefore, invaluable in certain cases, but are unfortunately only applicable to a small percentage, and even then can only deal with some of the lesions

Suiting the Remedy to the Case

No universal remedy has so far been proved to be reliable The specific and other general remedies which are useful in afebrile cases do not appear to be suitable for the toxæmic, for which hygienic remedies—rest, fresh air, &c—are still the most widely applicable An antitoxin that would cause passive immunisation without interfering with the processes of active immunisation would be a great boon in toxæmic cases Patients who suffer from pulmonary tuberculosis do not all lose ground for the same reasons In one it may be the digestion, in another the circulation that fails, so that in all but early stage cases more than one remedy would appear to be necessary

The Results of Treatment

To prove the value of a remedy in pulmonary tuberculosis it is not enough to show that improvement—or even recovery—has resulted under its use, for this is true of every one of the numerous remedies ever recommended, some of which are now discredited Since many factors influence the result besides the special remedy, and there is a natural tendency to recovery in most of our present population, this is quite intelligible, though often lost sight of

Present methods of treatment are capable of restoring to health in most of the early cases, and many of the more advanced, but they have the drawbacks that the treatment is insufficient in some cases, is necessarily prolonged, is sometimes highly inconvenient, and will usually only lead to a recovery which is dependent upon the after-conditions of life If, then, a new remedy can be shown to make the necessary treatment shorter, more widely reliable, more convenient, or more lasting and unconditional, it is well worth adopting This claim has been made on behalf of several remedies not universally accepted—notably for tuberculin—but owing to the imperfections of the tests applied has not been substantiated

Immediate or remote results—Unless the after-conditions are known and taken into account, the remote results are not a safe measure of the efficacy of treatment Survival is a measure, not merely of the value of treatment, but also (and much more) of the suitability of the after-conditions and of the permanent damage done to lungs and other organs Even after complete arrest of the tuberculosis, the life is below standard, and liable to be cut short by circumstances not directly connected with the original illness or its treatment

Estimation of Progress

There are two possible ways of recording progress either to record the progress made in a given time, or to record the time necessary to arrive at a given degree of improvement Each method has its convenience according to circumstances, but the latter is more precise when treatment is not arbitrarily limited, but is continued until the maximum benefit has been obtained

Progress in a given time—In this method the improvement effected in various respects will have to be summarised by some suitable classification One of the simplest is into (1) well, (2) better, (3) stationary, (4) worse, (5) dead It is, however, arbitrary, and does not distinguish (as it should) between local and general improvement A more complete classification, in which the terms are defined, was devised by the American National Association for the Prevention of Tuberculosis, with modifications by Lawrason Brown[3] This classifies the results into (1) apparently cured, (2) arrested, (3) improved, (4) unimproved or progressive, (5) dead This is quite convenient where the time of treatment is prolonged, but in many sanatoriums in this country the time of treatment is limited for most cases to two or three months, so that the results could only be classed under the last three headings

Measurement of time required is often possible when the foregoing method would be fallacious or inapplicable We may choose some definite sign of improvement, such as the disappearance of râles (if there is no mixed infection), of fever (resting or ambulant), of sputum, or tubercle bacilli in the latter More useful research could be done in this way, by noting the average time required with and without the special remedy in similar groups of patients than in searching for "remedies for consumption" when the time and conditions were inadequate for a fuller test

Space does not permit me to discuss the various signs and symptoms of improvement Some of these—such as gain in weight—are only applicable for limited periods Others—such as disappearance of sputum or of râles—are equivocal, and must be taken together with other circumstances in deciding whether they are signs of improvement or not When progress is slow, and the evidence obscure, other criteria should always be adopted as well as the usual clinical ones—notably the blood tests and the graduated Pirquet[4] Among the more useful blood tests may be mentioned the Arneth test, differential leucocyte counts (leucocytosis with increase of lymphocytes and of eosinophils is favourable), the sedimentation test, and some of the chemical tests One caution is necessary respecting physical signs These should be similarly estimated before and after treatment and in the controls, X ray findings are not comparable with those by ordinary clinical methods If both are not available, the latter is preferable in expert hands Care should also be taken to distinguish between consolidated and fibrosed areas I have known elaborate treatment employed in a case where there was no evidence of any active tuberculosis, only the results of past disease

---

[3] Jour Amer Med Assoc, Jan 30th, 1909

Conclusions

Recovery in pulmonary tuberculosis depends on so many variable factors that extreme care is necessary in estimating the value of a remedy in this disease, especially one which acts upon several parts of the body, or is reputed to have a general curative effect We must take into account the clinical state of the patient, points in the history enabling us to estimate his resisting power and the fierceness of the attack, the general conditions of life, including dominant hygienic factors, observance of ordinary "sanatorium" rules, and factors of climate, site, and quarters The remedy must be applied to a fairly definite group of patients in a definite and fairly uniform manner, and should be continued until there is reasonable probability of having attained the maximum benefit Controls should be chosen, of a similar nature, under similar conditions, excepting always the factor to be tested

Remote results are not reliable, because they depend not only on the original course of treatment, but also largely on the conditions of life and the amount of permanent damage to lungs and other organs before, during, and after treatment To estimate the immediate results we need a careful classification in which the terms are defined Where prolonged treatment is not available, valuable information may be obtained by estimating the average length of time necessary to attain some definite result, such as disappearance of fever or of râles Just as in pharmacological investigations the action of the remedy on each physiological system is noted, so should it be with the remedies of tuberculosis More useful conclusions are likely to be arrived at by studying the effect of any reputed "cure" on the individual factors of the disease than by merely recording "improvement" or "recovery," a conclusion which teems with fallacies

---

VENEREAL DISEASE IN BRITISH COLONIES

THE British Social Hygiene Council brought a number of recommendations before the recent Colonial Office conference To stamp out venereal disease, they said, the primary need is for medical men and women, specially qualified, to be placed in charge of antivenereal work with adequate facilities In appointing medical officers in the future the Colonial Office should demand of candidates an efficient knowledge of the diagnosis and treatment of venereal diseases, and study leave should be given to medical officers already employed to enable them to secure the necessary knowledge Where the appointment of a specialist was impracticable for some single small unit of the Empire, it might prove effective to appoint a specialist who could hold post-graduate courses in a number of centres who could devise and supervise special treatment facilities in each centre, who could act as adviser to the chief medical officers on the spot, and could promote a campaign for public enlightenment. Outlying parts of the Empire, it was pointed out, are paying 50 per cent more for neosalvarsan preparations than the institutions giving free treatment under the Ministry of Health in this country, combined action should be taken by the Colonies in the purchase of drugs The question of education was discussed, and it was proposed that as emergency measures, pending the adequate training of teachers, arrangements should be made between the Colonial Office and groups of colonies for visits to be paid by a biologist and a psychologist to the different units and for scholarships to be offered to enable selected teachers to take a full year diploma course which, it is hoped will shortly be available at the Universities of London, Wales (Aberystwyth), and Liverpool

Serious harm, according to representatives of the Council, is being caused to some foreign races by the circulation of suggestive films among peoples to whom Western customs and traditions are unknown The Council does not consider it sufficient that only those films to which the term "obscene" could be applied should be banned, but would wish the ban also to be applied to other European films that can be classed as "unsuitable"

A NEW DESIGN OF ULTRA-VIOLET LAMP

THE "Trinity" ultra-violet lamp designed and produced by the Medical Supply Association, enables the user to employ the radiation either from a mercury vapour burner or two carbons plain or cored, two tungsten rods or tungsten and carbon The mercury arc and any of the open arc combinations can be used simultaneously, though not on the one patient. The apparatus consists of a floor standard of the usual type, with circular resistance unit round the foot of the central column, and carrying a counter-weighted arm provided at each end with one of the familiar spherical aluminium hoods The arm has a good vertical travel and moves on ball bearings providing for horizontal movement Locking arrangements are also provided One hood contains a vacuum type mercury vapour burner consuming approximately three ampères The arc is struck by tilting the metal hood which is so weighted as to return to the normal running position This arrangement keeps the interior of the hood free from mechanism and facilitates the provision of a concave reflector, the angle of which can be adjusted to suit the position of the patient This reflector is made of a special metal claimed to have an unusually high reflective power

For local treatment, the whole lamp can be enclosed except for an aperture of the desired size, and ample ventilation appears to have been provided The other hood is used to house the open arc, which consists of two adjustable electrode holders, each having an adapter to take either tungsten rods or carbons of about 13 mm diameter The handles are well insulated and striking is performed by pushing in one of the electrodes till the points touch; on releasing the pressure, the points separate a definite distance by the action of a return spring and the arc can then be adjusted For local treatment, the front is rotated bringing into position a concentrating quartz lens The consumption of this unit is approximately 5 ampères Each unit is provided with its own resistance and switch

The apparatus is primarily designed for use on direct current mains, but when alternative current only is available, an electrolytic rectifier can be provided The design is ingenious and practical.

THE HYGIENE OF THE CHILD OF TEN

IT would be useful as well as interesting to have a complete series of monographs on the various epochs in the life of man, woman, or child, considered from the standpoint of physiology, psychology, and hygiene There are some excellent books somewhat of this kind such as Stanley Hall's "Adolescence" or Miss Drummond's "Round About Four Years, Old," but these authors were not medical and certain important aspects of their subject are passed over Of works by medical writers there are a fair number dealing with infants, but for later ages there are few

We have received a reprint of a thesis which Dr Theodore C Merrill, of Boston, U S A, recently presented at the University of Paris, dealing with the Hygiene of the Child of Ten He remarks on the importance of this age—or rather of the period from 7 to 13 years, it is, he says, "à la veille de la puberté," and the latest period of childhood during which it is still possible to correct defects Nevertheless, it has been neglected by hygienists Dr Merrill has been unfortunate in not having read the exhaustive study recently published in England, Dr James Kerr's "Fundamentals of School Health" His subject, moreover, is so large that it could only be compassed by either limiting its scope to the features peculiar to this age or by dealing with it generally without going into detail In the main, he has adopted the second course, and a good deal of his matter is of general application, for example, he includes a comparison of the climatic conditions of France and the U S A which is well set forth and interesting in itself, but can hardly be said to concern peculiarly the child of 10 He gives also a lucid collection of statistics on height and weight with an account of the Pelidisi formula and some figures on the distribution of thyroid insufficiency and its treatment, which show how widespread the trouble is He quotes from THE LANCET (1926, ii, 669) the statement of Dr R H Vercoe that children of 10 are particularly liable to rheumatism One of his sections is modestly called "Des banalités assez banales," but the critic would be wrong if he thought the precepts valueless For example, if the importance of a regular action of the bowel in children were realised, much trouble and illness in later life would be avoided, and if the futility of having the hair singed and the small value of many special soaps were appreciated much time and money would be saved Again, it is well known that "the pulse, respiration, and temperature are more readily modified in children than in adults by trifling causes and nervous influences" but if parents (and occasionally medical men) always kept this fact before them, they would be spared much needless anxiety

Some Problems
OF THE
MENSTRUAL FUNCTION,
WITH OBSERVATIONS ON THE RELATION OF THE GRAAFIAN FOLLICLE AND CORPUS LUTEUM TO PATHOLOGICAL UTERINE HÆMORRHAGE.

An Address read before the Edinburgh Obstetrical Society on May 11th, 1927,

By BECKWITH WHITEHOUSE, M S Lond,
Ch M Birm, F R C S Eng,

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN UNIVERSITY
OF BIRMINGHAM HONORARY GYNÆCOLOGICAL SURGEON,
GENERAL HOSPITAL, BIRMINGHAM

There is nothing. I think, more stimulating to research than to have work thoroughly discussed under the critical eye of friends A worker in his own den whether that den be the hospital ward or a pathological laboratory. is apt sooner or later to fall into a groove Theory is liable to become an obsession and without the therapeutic stimulus of free and open discussion the result of research may be but an abortion—the unfinished and incomplete effigy of what might have been a real and beautiful entity It is in this spirit, therefore that I venture to submit certain observations on the menstrual function which have interested me during my work in the Midlands

Now the phenomena associated with the menstrual function may be studied in various ways Briefly, these may be stated as follows —

(a) By a comparison with the sexual phenomena noted in other species in the mammalian tree.

(b) By a study of material obtained at operation at different periods in the sexual cycle, and especially during the actual menstrual function.

(c) By the investigation of the actual function especially of the menstrual discharge, both in health and disease

(d) By noting the effect both immediate and remote of excision of parts of the sexual apparatus at different periods of the sexual cycle.

(e) By the observation in animals and ' homo " of the effect of injecting various tissue extracts.

These are the lines upon which we are working in Birmingham and which as time goes on have altered many of my preconceived ideas with regard to menstruation.

The Nature of the Menstrual Function.

The first question that I propose to discuss is. ' What is the menstrual function in the genus homo ? ' The generally accepted view. of course. is that it is a preparation of the uterus for the reception of the fertilised ovum. In other words, that it corresponds to the stage of pro-œstrum in the lower *mammals* That this is not entirely correct I am firmly convinced from data which I shall shortly place before you In order to make the position clear, however it will be necessary to refer briefly to the phenomena associated with the sexual cycle in other mammalian types

The period of the year when physiological activity of the reproductive system in mammals occurs has been called by Heape the " sexual season " At other times in the majority of wild species the reproductive organs are quiescent. During the sexual season which, in the wild state, occurs usually but once a year, the female experiences a series of cyclical periods of sexual activity Each of these successive periods during the sexual season constitutes an " œstrus cycle," divided by Heape into four subsections .—

(1) Anœstrum, or period of rest.

(2) Pro-œstrum, or period of endometrial growth and functional activity.

(3) Œstrum or period of desire, when fertilisation is effected.

(4) Pregnancy, or " pseudo-pregnancy "

During the anœstrum *or rest period the uterus is* in a state of quiescence Its glands are small and the organ is relatively anæmic The ovaries, so far as the Graafian follicles are concerned are also inactive It is a period of slow growth and development of the follicles which do not appear on the surface of the ovaries until the succeeding stage of pro-œstrum.

With the advent of ' pro-œstrum ' or " coming on heat functional activity of the sexual apparatus is initiated The ripe follicles project on the surface of the ovary and coincidently with their full development the endometrium exhibits evidence of increased growth and vascularity. The glands secrete, and the congestion of the stroma is so great that rupture of the thin-walled capillaries occurs with extravasation of blood into the surrounding tissue. This extravasation and flushing of the endometrium with blood is so extreme that not only does it occasionally lead to disruption of the glands and the appearance of red cells in their lumina but also in some animals, as the bitch, to a partial breach of surface of the endometrium and the appearance of external hæmorrhage per vaginam. We *must note* however, that although pro-œstrum is always associated with increased vascularity of the endometrium and glandular activity it is only in a few mammalian types that hyperæmia is so extreme as to give rise to external hæmorrhage from the uterus The more common phenomena is profuse secretion of the glands only, with a slight superficial desquamation of the cornified cells of the vagina. The appearance of these cornified cells in the secretion contained in the vagina has been made use of by Papanicolau. Wright and Dodds. and others as evidence of pro-œstrum in their investigations of the sexual cycle in rodents

Pro-œstrum is followed directly by œstrum, which in the majority of mammals is the period when coition occurs. It is also in many animals, but by no means all, the point in the sex cycle when ovulation occurs from the *ripe follicle. Œstrum lasts* from a few hours, as in the sheep, to about a week in the case of the bitch It is interesting to note in types where no denudation of the endometrium occurs during pro-œstrum that œstrum is comparatively a short period as compared with other animals as the bitch, where regeneration of tissue is necessary. During œstrum activity of the uterine glands continues and the uterine *cavity contains much secretion* Leucocytes take the place of the ' cornified cells " in the vagina, and their presence is an indication of the onset of this stage.

Now, if fertilisation does not occur, a state of pseudo-pregnancy supervenes, which is of particular interest to us as gynæcologists. This state, in essential anatomical details so far as the ovary, uterus and mammary glands are concerned resembles a condition of true pregnancy. The variation is merely one of degree.

In the ovary the corpus luteum resulting from the ruptured Graafian follicle persists throughout pseudo-pregnancy and towards the end of the period assumes the yellow colour due to the lutein lipoid The uterus exhibits *increased* vascularity, and the endometrium. both stroma and glands, undergoes considerable hypertrophy. This hypertrophy in both macroscopic and microscopic detail is to be regarded as an early decidua. The retention of secretion of the uterine glands may, in fact, be the equivalent of what in pregnant ungulates is known as " uterine milk," a possible source of nutrition to the developing ovum In this connexion I would ask you to remember the high calcium content of the secretion of the corporeal uterine glands. If it is not required by pregnancy it is discarded, and this accounts for the high calcium content in the menstrual lochia of the human female

At the end of pseudo-pregnancy, the actual duration of which is a very variable quantity in different animals, a stage of involution sets in characterised by degeneration of the endometrium or decidua, and in some instances by definite necrosis associated with hæmorrhage In the bitch, whilst bleeding occurs at this stage also into the tissues of the endometrium, there is no external hæmorrhage In other mammals —e g , the cow—a definite post-œstral hæmorrhage occurs, forming the so-called "menstrual clot" This is thought by Hammond to coincide with the termination of a short pseudo-pregnancy, and he is probably right When the pseudo-pregnancy is short it will be readily understood that hæmorrhage is more likely to be a feature of the tissue necrosis that follows its termination, owing to the embryonic state of the pseudo-decidua

We therefore arrive at the very important observation that in the mammalia hæmorrhage from the genital tract can and does occur in different species at the following points in the sexual cycle

(1) During pro-œstrum, as a result of the local hyperæmia of the endometrium incidental to this physiological state —cf, the bitch

(2) At the end of pseudo-pregnancy, resulting from degeneration of the false decidua and necrosis of this structure —cf, the cow

In other types—e g , the sheep, sow, mare, and various rodents—no external hæmorrhage into the uterine cavity occurs at all, either during the stage of pro-œstral congestion or during involution at the end of pseudo-pregnancy Now the mammalia naturally fall into two well-defined groups —

(*a*) Species in which the sexual season is associated with but one complete œstral cycle—the so-called "mon-œstrus type" of Heape

(*b*) Animals in which there is a recurrence of short œstral cycles at regular intervals throughout the sexual season—the "poly-œstrus type"

Amongst poly-œstral types much variation exists, both in duration and kind, with regard to the various units of the œstral cycle Generally speaking, however, it may be said that the sex cycle of the poly-œstral animal differs from that of the mon-œstral in the following particulars —

1 Anœstrum may be absent, as in the primates

2 Pro-œstrum is short and, in practically all species, is characterised only by congestion of the endometrium with increased activity of the uterine glands, but *no external hæmorrhage*

(3) Œstrum is very short and may be only a matter of a few hours

(4) Pseudo-pregnancy is also abbreviated, and its termination may be associated with hæmorrhage from the uterine cavity

N B —The brief pseudo-pregnancy between the recurring short cycles of poly-œstral animals was wrongly regarded by Heape as being a short rest period and called by him the "di-œstrum" Using the same terminology Heape calls the short sex cycle of the poly-œstral mammal the "di-œstrus cycle"

Although the poly-œstral state occurs naturally in certain wild species, particularly rodents, it is a fact that in domestic types it appears to be the direct outcome of selective breeding, altered feeding, and changed environment Marshall has drawn attention to the fact that whilst the wild sheep is mon-œstral, the Scottish "blackface" in the Highlands has two di-œstral cycles in the sexual season The same breed under the improved conditions of the lowlands increases the cycles to five or six On the other hand various English breeds—e g , the "Dorset horn"—exhibit still further activity and frequently have two sets of lambs in the year With the merinos of New South Wales the di-œstral cycles succeed one another throughout the year and there is a complete absence of anœstrum The purpose of such extreme cyclical sex activity is, of course, to increase the possibility of pregnancy, and so promote the fecundity of the species The artificial development of the poly-œstral from the mon-œstral type as a result of feeding and environment is an interesting and important aspect of comparative physiology to the gynæcologist Recently Beaumont and Dodds have shown the importance which certain foods rich in vitamin E—e g , wheat, peas, lettuce &c —have upon the reproductive function It is, I think, rather an interesting coincidence that in the arid tracts of the Sahara the only sustenance available for the herds of goats is a food particularly rich in this vitamin—viz , the Alfa grass

OVULATION AND THE SEX CYCLE

Let us next consider the position that ovulation occupies in the sexual cycle In the majority of poly-œstral animals, rupture of the Graafian follicle occurs either during or shortly after œstrus In a few types —e g , the rabbit and cat—pro-œstrum and œstrum are apparently fused, and ovulation *only* occurs a few hours after coitus In the absence of coitus there is no dehiscence and no formation of a corpus luteum Under these conditions pseudo-pregnancy is absent and a prolonged œstrus passes insensibly into a state of anœstrum The unruptured follicles in the ovary become atretic and degenerate, with hæmorrhage into their cavities, a fact of considerable interest in a possible similar production of fibrocystic ovaries in the human female

When coitus occurs with a vasectomised male in the case of the rabbit or cat, a corpus luteum forms as usual, followed by the characteristic decidual development associated with pseudo-pregnancy

In the primates a degree of complexity is found with regard to the sexual cycle and ovulation which appears to have caused some difficulty in the proper interpretation and appreciation of the physiological facts accompanying the clinical phenomena In both man and monkeys the sexual life of the female from puberty to the menopause consists of a constantly recurring series of short œstral cycles There is no anœstrum, and the sexual cycles are consecutive and continuous There appears to be no doubt, however, that each cycle, as in other poly-œstral types, consists of a pro-œstrum, œstrum, and a pseudo-pregnancy

Although monkeys exhibit an unbroken succession of such cycles, it is very interesting to find that in certain types breeding is restricted to certain periods of the year It is evident, therefore, that *fertile* ovulation must be carefully considered as being a phenomenon apart from pro-œstrum. Corner has made the observation that in some monkeys when ovulation has not taken place and there is consequently no corpus luteum and pseudo-pregnancy, menstrual hyperæmia still occurs

Ovulation in the monkey, according to Corner's observations, takes place between the fourteenth and sixteenth days of the menstrual or sexual cycle This corresponds to the recent work on the human species by W. Shaw and others who, by a study of the life-history of the corpus luteum, have proved that ovulation in *homo* occurs between the thirteenth and seventeenth days of the menstrual cycle Ovulation in both man and monkeys is generally independent of coition I say "generally" because in some fibrocystic ovaries examined from single women I have on occasion failed to find any evidence of recent or remote lutein tissue May it be suggested that this is an atavistic state of sexual function ?

In both man and monkeys under domesticated and, therefore, artificial conditions, coitus occurs at any time during the menstrual cycle There is some evidence that a short œstral period does occur in the human female immediately after the menstrual function, but generally speaking it appears to be independent of the sexual cycle In fact, as we know, the sexual stimulus persists after complete ablation of the essential sexual organs, at any rate during the period of active sexual life As Marshall has pointed out, luxurious conditions favour the prolongation of œstrum, and "in some of the lower animals when stimulated by abundant food-supply (e g, domesticated rabbits) coition often occurs during early pregnancy, when it can serve no purpose in perpetuating the race."

In the human species the difficulties which arise in arriving at a proper conception of the menstrual function are minimised, I think, if we remember that pro-œstrum and œstrum provide one set of phenomena. Ovulation and pseudo-pregnancy provide another. In the human female the picture is complicated by the very simple fact that both sets of phenomena overlap.

Ovulation occurs between the thirteenth and seventeenth days of the menstrual cycle. This observation of Schroeder's and W. Shaw's I have repeatedly confirmed from the investigation of ovaries in relation with the menstrual cycle in a series of laparotomies performed for various indications.

From the date of ovulation a state of pseudo-pregnancy exists until its termination about the twenty-eighth day of the period, when necrosis of the menstrual decidua takes place and external hæmorrhage commences. Pari passu with the period of completion of the pseudo-pregnancy a state of pro-œstrum develops which reaches its acme also about the twenty-eighth day of the cycle, but persists during the abortion of the pseudo-pregnancy. This is followed at the conclusion of the menstrual hæmorrhage by a short œstral period, Nature's provision to promote fertilisation of the ovum about to be liberated from one of the succeeding follicles undergoing maturation.

The menstrual discharge in the human female, therefore normally contains blood derived from the endometrium as a result of two distinct factors.—

(a) Hæmorrhage resulting from necrosis of the endometrium caused by abortion of the pseudo-pregnant decidua.

(b) Blood produced by rupture of the capillaries caused by pro-œstral hyperæmia.

Appreciation of this fact—viz., that menstruation in the primates is a composite process involving two separate and distinct functions each subserving a special physiological purpose but overlapping the other in order to secure the maximum effect in the shortest time, throws considerable light upon what otherwise is a complex and difficult problem.

I will give you an analogy. The menstrual function may be compared with the stage of a theatre between two acts. One set of scene-shifters are busy removing the paraphernalia of the last scene whilst *another* are engaged in the same place and at the *same* time in reconstruction for the next act. Both are working together at top pressure and occasionally, I am afraid, one gets in the way of the other!

Now it is possible to study both sets of phenomena independently, and in considering the recent work that has been and is being done on the menstrual function, it is important to keep this distinction well to the front. My own observations, like those of Frankel, Halban, Schroeder, W. Shaw, and others, are more concerned with the investigation of what may be termed the "pseudo-pregnant" aspect of menstruation. On the other hand the work of Adler, Allen and Doisy, Marshall and Dixon and Dodds and Wright has been mainly in relation with the isolation and function of the hormone which produces "pro-œstrum" and "œstrum."

It is unnecessary to detail at any length the anatomical features of the human endometrium at different stages of the sexual cycle. The appearance of the so-called "constructive," "destructive," and resting stages are sufficiently well known. Too much stress, however, has, I think, been laid upon the sharp demarcation of these phases. It is far more important to remember that the endometrium in health from puberty to the completed menopause is never actually at rest. It is always either functioning or preparing to function. As Schroeder has pointed out there is evidence of commencing *secretory* activity of the uterine glands from about the thirteenth to the seventeenth day of the menstrual cycle. This activity increases, but as I have shown elsewhere, there is also an increasing *retention* of secretion as the cycle advances owing to constriction of the ducts by the developing decidual cells of the stratum compactum. It is not until some necrosis of the stratum compactum occurs on the first day of the menstrual function that there is a sudden out-pouring of the pent-up secretion.

As a matter of fact, a few dilated glands with "fern-like" processes are constantly to be seen in sections of the endometrium from the seventeenth day of the cycle onwards. They, of course, become more numerous as the length of the cycle increases owing to the construction of more ducts. In the fully developed menstrual decidua these dilated glands form a very distinct feature in transverse sections through the uterine cavity and constitute the "stratum spongiosum." With the complete development of the "stratum compactum" it will be understood that liberation of the corporeal secretion is not possible until necrosis of the superficial layers of the endometrium has removed the constriction of the ducts.

This is an important fact in view of the criticism that the formation of a menstrual clot is a normal part of the physiological mechanism of the menstrual function in the human female. It has been contended that the formation of a thrombus is impossible in the presence of a thrombolysin. The answer to this criticism is that the thrombolysin contained in the secretion of the uterine glands is not liberated until the thrombus is already formed.

That a menstrual clot in the uterine cavity *is* formed during the process of molecular necrosis of the menstrual decidua is certain; the original observation has been repeated on several occasions and it has been confirmed by W. Shaw and others. It is also equally certain that the menstrual lochia in health contains frequently no clots, although it is by no means uncommon to find in the discharge very small thrombi in process of disintegration. The discharge normally consists of the products of endometrial necrosis and autolysis with the secretion of the corporeal glands. It therefore contains no fibrin or fibrinogen, but it does contain a high percentage of calcium, possibly necessary should pregnancy occur, but otherwise discarded.

RELATION OF THE CORPUS LUTEUM TO THE MENSTRUAL DECIDUA

During the last quarter of a century a great deal of work has been done in the investigation of the structure and life-history of the corpus luteum, and especially the relation of this body to the menstrual function.

To Fränkel belongs the credit of first drawing attention to the relationship which exists between the *corpus luteum and menstruation*. By destroying the corpus luteum with the actual cautery he altered the menstrual rhythm and in the case of pregnant animals he produced abortion. As a result of these experiments Fränkel came to the conclusion that the function of the corpus luteum was to maintain the nutrition of the uterus from puberty onwards and to prepare the endometrium for the embedding of the ovum. He also thought that the lutein hormone was responsible for the local hyperæmia which accompanies menstruation. Fränkel's work was criticised chiefly on the basis that the cautery did not destroy all the lutein tissue in the ovary.

Halban therefore carried the investigation a step further by actually excising the corpus luteum in 40 cases. He found that uterine hæmorrhage occurred in 92.5 per cent. of the cases so treated. Strangely enough, however, this observer made no *attempt* to correlate the hæmorrhage with menstruation and, in fact, came to the conclusion that the menstrual function was not due to the corpus luteum but to ovulation. Halban thought that the lutein hormone exerted an inhibitory effect both upon menstruation and ovulation.

Meyer and Ruge, Miller and Schroeder, however, by studying the development of corpora lutea in relation with the anatomical appearances of the endometrium brought forward evidence in support of Fränkel's original thesis Schroeder, in fact, pointed out that whilst a young corpus luteum is always present at the commencement of endometrial activity, a mature corpus luteum is associated with what is generally recognised as the premenstrual state of the endometrium Furthermore, degeneration of the corpus luteum is found during the period of active endometrial necrosis

This was the position when, in 1926, I decided to repeat Halban's experiments, and at the same time to make a careful study of the endometrium should uterine hæmorrhage occur The result of my first observation, described in detail in the *Journal of Obstetrics and Gynæcology*, vol xxxiii, No 3, was to convince me that the effect of excision of the corpus luteum was to produce necrosis of the uterine endometrium Material was obtained which proved quite conclusively that the uterine hæmorrhage artificially produced on the eighteenth day of the menstrual cycle by excision of the corpus luteum 39 hours previously, was in essential details identical with that of the "menstrual period." I had, in fact, antedated the normal function by ten days More interesting still, the next "period" did not occur until 44 days later or only four days later than it would have occurred had no interference with the rhythm taken place Since this paper was published further observations have been made, and I am now able to carry the deductions a step further

Twelve more opportunities have occurred of excising the corpus luteum at periods varying between the seventeenth and twenty-fifth days of the menstrual cycle, and in every instance uterine hæmorrhage with endometrial necrosis has followed within 36–48 hours of the operation In each case also the next following menstrual period occurred within a few days of the normal period had no experimental interference taken place In other words, the only alteration of the rhythm was to antedate the menstrual period directly in proportion to the date on which removal of the corpus luteum was effected

Examination of the corpora lutea which were removed showed that this structure is *normally a cystic body*, and that, although there is much proliferation of the cells of the tunica granulosa with resultant thickening of the wall, a cavity is always present containing a clear fluid. The point of rupture of the parent follicle is usually evident on the surface of the corpus luteum as a small dimple or scar The aperture is apparently closed by approximation of the growing cells of the tunica granulosa, now accepted as being identical in type with the large lutein cells of the fully developed corpus

The corpus luteum increases in size, but maintains the same grey cystic appearance until immediately before the onset of the menstrual abortion Lipoid degeneration then occurs, characterised by the appearance of the yellow pigment in the cells and hæmorrhage in the cavity Hæmorrhage is the result of degeneration and fatty necrosis, and not a sequel of dehiscence of the follicle For this observation we are indebted to Wilfred Shaw, and with his views on this point I entirely agree

The cause of lutein degeneration in association with menstruation is still a problem My own view is that it is closely related with death of the unfertilised ovum I have recently suggested that it is the result of a "negative" phase initiated by the vaccine action of the unfertilised dead ovum and the cells of the corona radiata, cells morphologically identical with the large cells of the corpus luteum

Relation of the Graafian Follicle to the Menstrual Function

It is evident from the results of excision of the functionally active corpus luteum that this body exerts an important influence upon the development of the endometrium In fact, it appears that the growth of the menstrual decidua is entirely dependent upon its proper function, and that withdrawal of its active principle is followed within 48 hours by necrosis of the endometrium It appeared a matter of interest, therefore to study the effect of similar investigations in relation with the Graafian follicle before its rupture on the thirteenth day of the cycle

On three occasions the opportunity was taken to destroy developing follicles before maturity by "needling" both ovaries It was found on each occasion that uterine hæmorrhage commenced within 48 to 72 hours of the operation All the investigations were made before the thirteenth day of the menstrual cycle and in the absence of any functioning corpus luteum These observations were interesting, but were regarded as inconclusive, since it was thought possible that the uterine hæmorrhage might be the result of pro-œstral congestion resulting from the peritoneal absorption of a follicular hormone

A further series of four observations were made of excising large Graafian follicles either by double or single partial oophorectomy In three out of the four cases uterine hæmorrhage began within 72 hours of the operation In these three cases the excision took place between the tenth and thirteenth days of the cycle In the patient where no hæmorrhage occurred the operation was performed on the seventh day of the cycle or three days after the termination of a four-day period It was concluded, therefore, from this second series of observations that the uterine hæmorrhage occurring in the first group *was* due to the destruction of the follicle and not to the absorption *of follicular hormone*

In the case of the three patients whose ovaries had been "needled" the opportunity was taken of collecting some of the liquor folliculi and amounts varying between ½ c cm to 1 c cm were injected intravenously into other patients without producing any *obvious clinical effect* The uterine hæmorrhage produced by excision of Graafian follicles differed somewhat in type from that produced by removal of the corpus luteum It was comparatively slight, somewhat irregular, and continued seven to ten days —in fact, longer than the usual menstrual bleeding and comparable with the pathological type which I have called "menostaxis" as distinct from "menorrhagia"

These observations point to the fact that not only the corpus luteum but also the Graafian follicle is responsible for the growth of the endometrium, which certainly appears logical *owing to the development* of the former from the cells of the latter

The follicular hormone, therefore, appears to be a complex body possessing more than one active principle That it contains a body capable of producing œstrus in the lower animals has been proved conclusively by the work of Adler, Fellner, Herrmann and Fränkel, Allen and Doisy, Stockhard and Papanicolau Recently Dickens, Dodds, and Wright have isolated a physiological principle in the form of an oil which stimulates œstrus in rats and which has a marked depressor action

It is only reasonable to suppose that a similar œstrus-producing principle is present in the ovaries of women, although actual physiological proof is as yet required There is certainly no evidence available to prove that the intravenous injection of liquor folliculi has any influence in the production of the menstrual hæmorrhage in the human female In fact my observations all tend to show that the uterine bleeding is produced as the result of endometrial necrosis by the withdrawal from the circulation of some principle elaborated by the follicle and the corpus luteum which is essential for its development

The œstrus-producing hormone of Dickens, Dodds, and Wright obtained from pigs' ovaries was not, however, confined to the liquor folliculi It was present in extracts from the whole ovaries, and these workers state definitely that their findings do not support the contention of Allen and Doisy that the active principle is mainly a feature of the liquor folliculi Allen and Doisy themselves did not find it in extracts of the corpus luteum On the other hand, Samson Wright has informed me that he and his co-workers have isolated the hormone not only from the ovaries but also from the placenta and various other tissues submitted to them from the gynæcological operating theatre

In 1914 I called attention to the presence of an œstrus-producing hormone in the uterine secretion of rodents. and it seems probable that the existence of this active principle is only dependent upon the ovaries in a secondary sense It may. indeed, be produced in tissues other than the ovaries—e g. the thyroid—as is evidenced in the human species by the persistence of the sexual instinct after complete ablation of the uterus and ovaries or the occasional occurrence of endometrial congestion and hæmorrhage at a considerable period after double oöphorectomy.

The result of clinical investigation on human ovaries has brought to light therefore the following facts —

(1) That removal of the physiologically active corpus luteum at any stage of its development during the menstrual cycle is followed directly by molecular necrosis of the endometrium.

(2) That destruction of mature Graafian follicles before rupture is also followed by endometrial necrosis

(3) That excision of mature Graafian follicles likewise results in necrosis of the endometrium

(4) That injection of liquor folliculi does not produce uterine hæmorrhage

It is evident. therefore that both the Graafian follicle and the corpus luteum contain an active principle which is essential for the proper development and function of the endometrium If it is withdrawn from the circulation necrosis of the superficial layers of the endometrium ensues On the other hand, its constant stimulus promotes development of the endometrium until the mature decidua is formed

This active principle is probably produced from the cells of the tunica granulosa and inasmuch as it is a feature of the secretion of both the follicle and corpus luteum neither the name ' folliculin " nor " lutein " appears entirely suitable As an alternative I suggest the term " *ovarin* " to designate the hormone which is essential for the proper growth and function of the endometrial stroma.

The recently introduced term " œstrin " should be reserved for the other œstrus-producing hormone of the follicle which experiment shows is not present in the corpus luteum " Œstrin " is probably responsible for the pre-menstrual congestion and functional activity of the uterine glands " Ovarin ' on the other hand controls the growth of the stroma. and the withdrawal of this hormone from the circulation initiates endometrial necrosis with hæmorrhage from the congested stroma

The significance of this conception of the menstrual function has, I think an important corollary in the explanation of some cases of pathological uterine hæmorrhage If endometrial necrosis ensues upon the destruction or excision of the maturing follicle and the corpus luteum, it is reasonable to suppose that similar trauma effected by disease is followed by like results This is. indeed. the case and many instances of irregular uterine hæmorrhage in association with fibrocystic ovaries prolapsed ovaries and chronic inflammatory disease of the uterine adnexa are I think due to the death of maturing Graafian follicles and pathological corpora lutea Recently I have investigated several ovaries from cases of large fibroids where metrostaxis as well as menorrhagia has been a feature and in every instance I have found large cystic unruptured follicles as well as corpora lutea in various stages of degeneration The follicular or lutein cysts in many instances contained blood It seems probable. therefore that in these cases both the uterine hæmorrhage and the sterility have a common ovarian origin The sterility is due to unruptured follicles and the metrostaxis to the periodical irregular cutting off of the supply of " ovarin " It is in these and similar cases infinitely better for a Graafian follicle never to develop at all. Partial maturity with subsequent death is probably always associated with endometrial necrosis and hæmorrhage, such as is commonly found during the years of the menopause, and at puberty Excess of the " ovarin " hormone is, I think, one of the causes of precocious decidual development and, as I have shown elsewhere, it appears to be a factor in the production of severe menstrual pain.

CONCLUSION.

In conclusion may I say just a word with regard to the therapeutic value of so-called ovarian and lutein extracts. I am afraid that I cannot claim hitherto to have had any considerable and *sustained* success with any single extract at present on the market This is more particularly the case in the control of irregular functional uterine hæmorrhage —metrostaxis in other words Every now and again one has an apparent success, and then in another case with precisely a similar pathological picture and using the same commercial preparation no result whatsoever is obtained Now. I think that the cause of these discrepancies lies in the fact that in the first place whole animal ovaries are used in the preparation of the extract In the second place I doubt very much whether many commercial extracts are made when " ovarin ' is present in the organs used For a preparation to have any physiological action in the prevention of premature endometrial necrosis and, therefore hæmorrhage it should be made either from *mature* Graafian follicles or from *functioning* corpora lutea—not the degenerated yellow bodies " which are but the empty shell and from which the inmate has escaped.

Not until extracts are always made from animals' ovaries during either pro-œstrum or the early months of pregnancy do I expect on physiological grounds. to obtain uniformly satisfactory therapeutic results.

SOME DIFFICULTIES IN THE DIAGNOSIS OF ACUTE LEUKÆMIA.

BY J. B DAVEY, M B LOND, D.T.M LIVERP.,
HONORARY PATHOLOGIST TO THE CHELTENHAM GENERAL AND EYE HOSPITAL,
AND
L E H WHITBY, *M C*, M.B CAMB, D P H,
ASSISTANT PATHOLOGIST, THE MIDDLESEX HOSPITAL

IN reviewing the clinical and pathological aspects of the six cases of acute leukæmia that have come to our notice in the past 18 months the increase in the incidence of all types of leukæmia has been rendered more noticeable. It seems unlikely that the advent. within so short a time. of three cases of the rare acute lymphatic type of the disease should be coincidence During the same period of the more chronic forms no less than 13 cases of lymphatic leukæmia and 11 cases of myelocytic leukæmia have been examined and diagnosed at the Middlesex Hospital whilst Prof Sholto Douglas[1] has drawn attention to the large numbers of cases occurring at Sheffield during recent years and suggested the possibility of the disease being sometimes epidemic.

In describing and labelling these cases we are at the outset confronted with the lack of agreement of various authorities with regard to the incidence of the various forms and the means of differentiating them. Some of the opinions may be quoted here. Thursfield[2] does not distinguish the various types of acute leukæmia, and says " the lymphocyte of acute leukæmia is not the lymphocyte of the normal blood and is probably (Cabot) a marrow rather than a lymph gland cell " Gulland and Goodall[3] state that myeloblastic (acute) leukæmia is the more frequent and that acute lymphatic leukæmia is very rare and only distinguished from the myeloblastic variety by the Jenner-Giemsa method of staining—a process which the authors describe as “a rather tricky exercise in staining gymnastics” With this opinion we concur

In another publication Gulland[4] writes that “the acute myeloblastic and lymphatic forms (of leukæmia) are probably the most common,” but at a later date he[5] is reported as stating, “I am becoming somewhat sceptical of the existence of a really acute lymphatic form” He explains this attitude by the fact that many of the myeloblastic cases are definitely mixed at the outset and only become purely myeloblastic in the terminal stage MacCallum's[6] experience is that acute lymphoid leukæmia is more common than the chronic form but that the cells are larger and that some cases formerly classified as acute lymphatic are now known to be myeloid Todd,[7] under acute myelogenous leukæmia, says, “the predominating leucocyte is the most immature member of the bone-marrow series—i e, the myeloblast” He mentions that in some cases the cells are so very immature that the oxidase test fails, and it may be impossible to distinguish the disease from acute lymphatic leukæmia

A consideration of the origin of the various forms of leucocyte might be expected to throw some light on the immature cells found in the leukæmias, but here again there are different schools of thought—some adhering to a monophylitic and others to a polyphylitic theory. The subject is therefore one of some difficulty, and we can only hope with Gulland that some more satisfactory method of differentiating large immature leucocytes than the Jenner-Giemsa stain and the oxidase reaction will be devised We consider Lambright's[8] method of oxidase staining a great improvement on Goodpasteur's, and we are indebted to Dr J Allman Powell for drawing our attention to the method.

With these cases of leukæmia we have included one of glandular fever for, as the account will show, it presented in the early stages very real difficulties of diagnosis, and it is possible that sporadic cases such as the one described are more common than is supposed

CASE 1 *Acute Lymphatic Leukæmia* —A man, aged 53, was admitted to the Middlesex Hospital on June 4th, 1926, under Dr R A. Young He died five days after admission, the duration of life from the initial symptoms of headache and sweating being six weeks He was constipated throughout his whole illness and whilst in hospital enemata produced only small blood-stained results

On admission the skin was of pale lemon colour, the mucous membranes were pale, there were purpuric spots on the abdomen, and a large subcutaneous hæmorrhage under the right eye There was profuse hæmaturia (which had been present for two days prior to admission) and bleeding from the gums The spleen was just palpable and there was tenderness below the liver There was no glandular enlargement Temperature 99° F, pulse 90, respirations 26

During the five days the patient was under observation he became progressively weaker, vomited frequently, and had a subnormal swinging temperature Blood cultures were sterile and the only blood count performed gave the following result hæmoglobin, 28 per cent, red cells, 1,104,000, colour-index, 1 3, leucocytes, 10,200, polymorphonuclears, 26 per cent, lymphocytes, 68 per cent; large mononuclears, 6 per cent Two normoblasts per 100 leucocytes, poikilocytosis, and a fair number of polychromatic cells About 75 per cent of the lymphocytes were of large-cell type and large numbers of cells consisted only of “smeared nuclei” Goodpasteur's oxidase stain gave a negative result for oxidase granules

This is a typical case of acute leukæmia and it is noteworthy that the patient was a medical man who had worked with X rays for many years Gulland[4] records a case of a woman who had extensive X ray treatment for malignant metastases and who had a large spleen with a blood picture of acute myelocythæmia, the blood count and spleen returned to normal after cessation of the X ray treatment It is possible, therefore, that our case resulted from the prolonged X ray exposure inducing a leucoblastic crisis

Many hæmatologists deny the existence of an acute lymphatic leukæmia of large-celled type owing to the acknowledged difficulty in distinguishing the cells from myeloblasts Oxidase staining is admittedly often unsatisfactory, but when carefully controlled with normal and with known pathological blood it is certainly of value In diagnosing this case as acute lymphatic leukæmia rather than myeloblastic, we base our opinion on the negative oxidase reaction, the presence of “smeared nuclei,” and the scantiness of abnormal red cells, particularly megaloblasts and macrocytes—a factor usually well marked in myeloblastic and myelocytic leukæmia There is no doubt that this case was not a terminal phase of the more chronic type as the patient, on account of his occupation, had had his blood examined at regular intervals

CASE 2

Date in 1926	Hæmoglobin per cent	Red cells.	Colour index	Leucocytes	Polymorphonuclear per cent	Lymphocytes per cent	Nucleated reds	Remarks
April 7th	30	1,176,000	1 4	196,800	2	98	0	Poikilocytosis present Predominant cell large lymphocyte (70 per cent)
,, 21st	30	1,050,000	1 5	222,000	1	99	0	Poikilocytosis Large lymphocytes (70 %)
,, 29th	20	620,000	1 7	167,000	1	99	2 megaloblasts	Poikilocytosis and macrocytes Radium applied five days previous to count Large lymphocytes (50 per cent)
May 6th	22	770,000	1 5	135,000	3	97	2 megaloblasts	Poikilocytosis and macrocytes Predominant cell small lymphocytes (60 %)
,, 14th	16	1,700,000	0 5	96,600	1	99	2 megaloblasts 1 normoblast	Poikilocytes, macrocytes Death five days later Predominant cell large lymphocytes (70 per cent)

CASE 2 *Probably the Terminal Crisis of a Chronic Lymphatic Leukæmia* —A man, aged 32, was admitted to the Middlesex Hospital on April 7th, 1926, under Dr C E Lakin He died six weeks afterwards, the duration of symptoms prior to admission being three weeks He had first noticed bleeding from the gums, bilateral parotid swellings, sweating, loss of hearing, and increasing weakness.

On admission the gums were swollen, red, and bleeding, perspiration was profuse, and the patient was very deaf Temperature 100° F, pulse 140, respirations 24 The spleen was greatly enlarged and the liver was palpable one fingerbreadth below the costal margin Cervical, axillary, and inguinal glands were enlarged and the tonsils and adenoids (probably accounting for the deafness) were very much hypertrophied Retinal hæmorrhages were present All the glandular swellings, including the spleen, were remarkably soft

The clinical course of the case was marked by an evening temperature varying from 100° to 101 5°, periodic attacks of dyspnœa, enlargement of the veins over the chest, and obstinate bleeding from the gums

Treatment included mouth washes, liquor arsenicalis, and the application of radium over the splenic area but the latter resulted in so great a destruction of red cells that it was discontinued

Blood cultures were sterile The sedimentation of red corpuscles was 7 5 c cm There was a very marked thrombopenia and a great tendency for the blood to agglutinate as soon as a drop was placed on a slide The patient belonged to Group II of the blood groups In view of the marked auto-agglutinating power of his serum, it was tested against normal red cells of Group II, but without any effect The record of blood examinations was as under —

As in Case 1, the predominant cell was (with the one exception commented on below) always a large lymphocyte, and of these quite 50 per cent. were present as "smeared nuclei" Both Goodpasteur's and Lambright's oxidase staining reactions were negative

The most interesting feature of the case was the result of the application of radium to the splenic area The rather drastic effect on the red cells was not unexpected, but the marked alteration in the leucocytic picture—from large to small lymphocyte predominance—was not foreseen The blood picture reverted to its former type a week later—that is, within 20 days of the application of radium

In assuming the case to be the terminal phase of an old-standing case rather than a primary acute leukæmia, we are influenced by the clinical and hæmatological findings rather than by the history Chronic lymphatic leukæmia often exists for years without symptoms, and it is probable that most cases which have high leucocyte counts and large spleens are of long standing The changes in the red cells were characteristic of lymphatic rather than myeloblastic—viz, reduction in numbers and in hæmoglobin rather than by the appearance of grossly abnormal cells

CASE 3 *Acute Myeloblastic Leukæmia* —A man, aged 34, was admitted to the Middlesex Hospital on Feb 4th, 1925, under Dr C E Lakin He died two weeks after admission, the time from the onset of symptoms to death being five weeks He first attended the dental hospital on account of swelling and bleeding of the gums and soon after noticed a swelling in the neck which was followed by purpuric spots on the abdomen

On admission the gums were necrotic and bleeding, there were large, soft glands in the neck and a few small discrete, hard, painless glands in the axillæ and groins, there were purpuric spots on the abdomen and legs The spleen was palpable two fingers-breadth below the costal margin Temperature 101° F, pulse 104, respirations 22 The clinical course was marked by an evening rise of temperature reaching 101°, and progressive necrosis of the gums There was suppression of urine during the last 48 hours of life Treatment consisted of mouth washes, arsenic, and later, ferri et ammon cit

Blood cultures were sterile Cultures of the pharynx grew *B proteus vulgaris* and streptococci A blood count ten days before death showed hæmoglobin, 58 per cent, colour-index, 0 9, red cells, 3,200,000, leucocytes, 112,800, polymorphonuclears, 11 per cent., promyelocytes, 11 per cent, non-granular cells showing nucleoli, 34 per cent, non granular cells without nucleoli, 42 per cent, large mononuclears, 2 per cent. By Goodpasteur's stain the percentage of oxidase containing leucocytes was 43, macrocytes numerous, 4 megaloblasts per 100 leucocytes

Post mortem Examination —General glandular enlargement, particularly in the cervical region where the glands were soft and hæmorrhagic Liver, 72 oz, spleen, 16 oz, kidneys, each 12 oz —enlarged and pale with changes in the cortex and hæmorrhages in the pelves, causing obstruction on both sides, stomach contained altered blood and showed petechial hæmorrhages The intestines showed hypertrophied lymphoid tissue with a few scattered petechiæ on the mucous membrane, there was great hyperplasia of the lymphoid tissue at the back of the tongue The heart showed myocardial degeneration with a few scattered petechiæ on the pericardium Sections of the liver, kidney, intestine, spleen, and glands showed extensive infiltration with myelocytes and promyelocytes. No lymphatic infiltration was evident

Comment on this case is practically confined to the blood count, as the post-mortem sections gave a clear indication of its myeloblastic nature

In analysing the differential count, the difficulty arose as to whether the "non-granular cells without nucleoli" were myeloblasts or large lymphocytes Goodpasteur's stain was in this case no definite help, though the high percentage of oxidase containing leucocytes confirmed the fact that most of the non-granular cells were myeloblasts It is not improbable, in view of the extensive lymphatic hyperplasia found post mortem, that at one phase of the disease it was of mixed type and that some, if not all, of the non-granular cells without nucleoli were lymphocytes. The marked changes in the red cells, despite a relatively small reduction in numbers, was a point in favour of myeloblastic rather than lymphatic leukæmia The relatively small splenic enlargement influenced the diagnosis of primary acute myeloblastic leukæmia rather than the terminal phase of a chronic disease The case shows features which contrast with those of Case 6

CASE 4 *Acute Lymphatic Leukæmia* —A single woman of 38 came under Mr J C R Braine-Hartnell in January, 1926, with an enlarged gland in the neck which had been present for one month A week later other glandular enlargements developed in the neck, petechiæ appeared, and there was bleeding from the gums There was no splenic enlargement. A blood examination gave the following result hæmoglobin, 75 per cent, red cells, 1,600,000, colour-index, 0 8, leucocytes, 21,940, polymorphonuclears, 32 6; lymphocytes, 58 0, large mononuclears, 2 8, neutrophil myelocytes, 3 4, transitional forms, 3 4, 5 normoblasts per 100 leucocytes Her condition rapidly deteriorated and a blood examination 11 days later showed hæmoglobin, 70 per cent, red cells, 1,395,000, colour-index, 0 8, leucocytes, 26,300, polymorphs, 13 7, lymphocytes, 70 0, large mononuclears, 2 0, eosinophils, 0 3, mast cells, 0 7, transitional forms, 4 3, 12 5 normoblasts per 100 leucocytes The differential count was complicated by the presence of many "smeared nuclei" and the predominant lymphocyte was of large type The patient died after a profuse uterine hæmorrhage three days later The total time from when the glandular enlargement was first noticed to death was therefore seven weeks

We base our opinion that this was an acute lymphatic leukæmia on the low leucocyte count, the differential count, the absence of splenic enlargements, and the absence of gross changes in the red cells

CASE 5 *Acute Lymphatic Leukæmia in a Child* —A girl, aged 2 years 9 months, was admitted to the Cheltenham General Hospital under the care of Dr F J Lidderdale on Nov 13th, 1925 She died on Jan 1st, 1926 The history related that five weeks before admission she had a fall from a sofa, having been perfectly well up to that time; a week later she complained of pain in the back and abdomen, she then "caught a cold" and her mother discovered swellings in the neck and armpits She had difficulty in breathing and was brought to the hospital on Nov 6th when she had definite stridor and cyanosis and looked very ill On admission to hospital seven days later her general condition was better Tubular breathing and some crepitations were present at the base of the left lung and there was some dyspnœa The abdomen was prominent and the spleen much enlarged and hard, but not tender The axillary, cervical, and inguinal glands were enlarged, firm, and discrete She had frequency of micturition and the urine which was passed about every 10 minutes was loaded with urates The temperature was subnormal for the greater part of her illness, but on Dec 29th it rose to 101 8° and thereafter varied from 99° to 101° On admission a blood examination showed hæmoglobin, 56 per cent, red cells, 5,300,000, colour-index, 0 5, leucocytes, 109,000, polymorphonuclears, 6 8, lymphocytes, 87 6; large mononuclears, 2 4, mast cells, 0 4, myeloblasts, 2 0, neutrophil myelocytes, 0 4, transitionals, 0 1; 3 normoblasts and 0 8 megaloblasts per 100 leucocytes. Of the lymphocytes, 63 8 were small and 23 8 large Films made six days later and stained by Goodpasteur's oxidase method showed 96 3 without oxidase and 3 7 with

Post mortem, 12 hours after death —Ulcerated hæmorrhagic zones at the nail bed of each thumb and some of the fingers A small intracutaneous hæmorrhage in the right frontal region Lymphatic glands in the anterior and posterior cervical triangles, the axillæ and groins were much enlarged Blood was liquid in all parts of the body Spleen, weight 12 oz, extended below the umbilicus, was firm and crushed strawberry colour on section, Malpighian bodies not distinguishable Liver 2 lb 10 oz, was pale on section. Right kidney 2½ oz, left kidney 1½ oz, with red fat in the renal pelvis Alimentary tract showed no enlarged Peyer's patches Left pleura contained 1 pint and the right 6 oz. of a blood-stained fluid Left lung, lower lobe, collapsed. The ridges of fat between ribs and pleura were enlarged and red in colour and formed small sessile masses projecting into the pleural cavity Heart muscle firm and pale Valves normal Several small hæmorrhages in the visceral pericardium Under the sternum a greyish-white mass, showing small hæmorrhages on section, extended from the manubrium down over the heart, but neither lymphatic glands nor thymus could be detected on naked-eye examination Sections of this substernal mass showed a loose connective the Jenner-Giemsa method of staining—a process which the authors describe as "a rather tricky exercise in staining gymnastics" With this opinion we concur

In another publication Gulland [4] writes that "the acute myeloblastic and lymphatic forms (of leukæmia) are probably the most common," but at a later date he [5] is reported as stating, "I am becoming somewhat sceptical of the existence of a really acute lymphatic form" He explains this attitude by the fact that many of the myeloblastic cases are definitely mixed at the outset and only become purely myeloblastic in the terminal stage MacCallum's [6] experience is that acute lymphoid leukæmia is more common than the chronic form but that the cells are larger and that some cases formerly classified as acute lymphatic are now known to be myeloid Todd,[7] under acute myelogenous leukæmia, says, "the predominating leucocyte is the most immature member of the bone-marrow series—i e, the myeloblast" He mentions that in some cases the cells are so very immature that the oxidase test fails, and it may be impossible to distinguish the disease from acute lymphatic leukæmia

A consideration of the origin of the various forms of leucocyte might be expected to throw some light on the immature cells found in the leukæmias, but here again there are different schools of thought—some adhering to a monophylitic and others to a polyphylitic theory The subject is therefore one of some difficulty, and we can only hope with Gulland that some more satisfactory method of differentiating large immature leucocytes than the Jenner-Giemsa stain and the oxidase reaction will be devised We consider Lambright's [8] method of oxidase staining a great improvement on Goodpasteur's, and we are indebted to Dr J. Allman Powell for drawing our attention to the method.

With these cases of leukæmia we have included one of glandular fever for, as the account will show, it presented in the early stages very real difficulties of diagnosis, and it is possible that sporadic cases such as the one described are more common than is supposed

Case 1 *Acute Lymphatic Leukæmia* —A man, aged 53, was admitted to the Middlesex Hospital on June 4th, 1926, under Dr R A. Young He died five days after admission, the duration of life from the initial symptoms of headache and sweating being six weeks He was constipated throughout his whole illness and whilst in hospital enemata produced only small blood-stained results

On admission the skin was of pale lemon colour, the mucous membranes were pale, there were purpuric spots on the abdomen, and a large subcutaneous hæmorrhage under the right eye There was profuse hæmaturia (which had been present for two days prior to admission) and bleeding from the gums The spleen was just palpable and there was tenderness below the liver There was no glandular enlargement Temperature 99° F, pulse 90, respirations 26

During the five days the patient was under observation he became progressively weaker, vomited frequently, and had a subnormal swinging temperature Blood cultures were sterile and the only blood count performed gave the following result hæmoglobin, 28 per cent ; red cells, 1,104,000, colour-index, 1 3, leucocytes, 10,200, polymorphonuclears, 26 per cent, lymphocytes, 68 per cent, large mononuclears, 6 per cent. Two normoblasts per 100 leucocytes, poikilocytosis, and a fair number of polychromatic cells About 75 per cent of the lymphocytes were of large-cell type and large numbers of cells consisted only of "smeared nuclei" Goodpasteur's oxidase stain gave a negative result for oxidase granules

CASE 2

Date in 1926	Hæmoglobin per cent	Red cells	Colour index	Leucocytes	Polymorphonuclear per cent	Lymphocytes per cent	Nucleated reds	Remarks
April 7th	30	1,176,000	1 4	196,800	2	98	0	Poikilocytosis present Predominant cell large lymphocyte (70 per cent)
„ 21st	30	1,050,000	1 5	222,000	1	99	0	Poikilocytosis Large lymphocytes (70 %)
„ 29th	20	620,000	1 7	167,000	1	99	2 megaloblasts	Poikilocytosis and macrocytes Radium applied five days previous to count Large lymphocytes (50 per cent)
May 6th	22	770,000	1 5	135,000	3	97	2 megaloblasts	Poikilocytosis and macrocytes Predominant cell small lymphocytes (60 %)
„ 14th	16	1,700,000	0 5	96,600	1	99	2 megaloblasts, 1 normoblast	Poikilocytes, macrocytes Death five days later Predominant cell large lymphocytes (70 per cent)

This is a typical case of acute leukæmia and it is noteworthy that the patient was a medical man who had worked with X rays for many years Gulland [4] records a case of a woman who had extensive X ray treatment for malignant metastases and who had a large spleen with a blood picture of acute myelocythæmia, the blood count and spleen returned to normal after cessation of the X ray treatment It is possible, therefore, that our case resulted from the prolonged X ray exposure inducing a leucoblastic crisis

Many hæmatologists deny the existence of an acute lymphatic leukæmia of large-celled type owing to the acknowledged difficulty in distinguishing the cells from myeloblasts Oxidase staining is admittedly often unsatisfactory, but when carefully controlled with normal and with known pathological blood it is certainly of value In diagnosing this case as acute lymphatic leukæmia rather than myeloblastic, we base our opinion on the negative oxidase reaction, the presence of "smeared nuclei," and the scantiness of abnormal red cells, particularly megaloblasts and macrocytes—a factor usually well marked in myeloblastic and myelocytic leukæmia There is no doubt that this case was not a terminal phase of the more chronic type as the patient, on account of his occupation, had had his blood examined at regular intervals

Case 2 *Probably the Terminal Crisis of a Chronic Lymphatic Leukæmia* —A man, aged 32, was admitted to the Middlesex Hospital on April 7th, 1926, under Dr C E Lakin He died six weeks afterwards, the duration of symptoms prior to admission being three weeks He had first noticed bleeding from the gums, bilateral parotid swellings, sweating, loss of hearing, and increasing weakness.

On admission the gums were swollen, red, and bleeding, perspiration was profuse, and the patient was very deaf Temperature 100° F, pulse 140, respirations 24 The spleen was greatly enlarged and the liver was palpable one fingerbreadth below the costal margin Cervical, axillary, and inguinal glands were enlarged and the tonsils and adenoids (probably accounting for the deafness) were very much hypertrophied Retinal hæmorrhages were present. All the glandular swellings, including the spleen, were remarkably soft

The clinical course of the case was marked by an evening temperature varying from 100° to 101 5°, periodic attacks of dyspnœa, enlargement of the veins over the chest, and obstinate bleeding from the gums

Treatment included mouth washes, liquor arsenicalis, and the application of radium over the splenic area, but the latter resulted in so great a destruction of red cells that it was discontinued

Blood cultures were sterile The sedimentation of red corpuscles was 7 5 c cm. There was a very marked thrombopenia and a great *tendency* for the blood to agglutinate as soon as a drop was placed on a slide The patient belonged to *Group II of* the blood groups In was a comparatively small but gradual increase in the total lymphocytes; the differences were the absence of destructive changes in the red cells and the decline in numbers of lymphocytes with clinical improvement

It is noteworthy that glandular fever is frequently termed "infective mononucleosis," which implies an increase in the mononuclear cells Such a term is a misnomer in that the increase occurs in the lymphocytes and not the large mononuclear cells

In studying the lymphocytes of this case, one observed that the nucleus was eccentrically located and sometimes reniform. The cytoplasm was strongly basophil, contained azur granules and sometimes showed vacuoles The average size of cells was 14μ 13μ and of its nucleus 12μ × 10 25μ Lambright's stain was of considerable value.

No connexion with any other case of glandular fever could be traced nor did any inmate of the house in which the patient was nursed contract the disease The condition of the patient on June 20th gave cause for great anxiety, yet the impression gained from text-book descriptions of the disease is that of a mild pyrexial condition occurring in epidemics amongst children Our case illustrates that the disease may occur sporadically amongst adults as a severe illness with a protracted convalescence. Whilst this case was running its course there was a series of cases of illness characterised by pyrexia reddened fauces and marked cervical glandular enlargement at one of the schools in the town Two of these cases were examined and their leucocyte counts were 20.800 and 12.170 but the increase was of polymorphonuclear type.

Summary and Conclusions.

Acute leukæmia is fatal from a circle of causes; the leukæmic process invades the bone-marrow to the exclusion of erythroblastic tissue, and the accompanying hæmorrhages result in an anæmia which the reduced erythroblastic tissue cannot make good. Death occurs from anæmia and exhaustion unless the hæmorrhages previously obstruct the functions of a vital organ, such as the kidney (Case 3)

Assistance in distinguishing acute lymphatic leukæmia from acute myeloblastic leukæmia, other leukæmias, and glandular fever is given by the following points:—

1. *Splenic enlargement*—This is not marked in the acute lymphatic leukæmia of adults but is observed in children. It is not usually marked in acute myeloblastic leukæmia. Gross splenic enlargement in an adult suggests the terminal phase of a chronic or subacute leukæmia, either lymphatic or myelocytic, rather than a primary acute disease Splenic enlargement is present in some cases of glandular fever.

2 *Duration of symptoms* particularly hæmorrhages In the primary acute leukæmias the symptoms rarely exceed a few weeks If the symptoms have been present for a short time only and there is gross splenic enlargement, the probability is that the case is the terminal phase of a lymphatic rather than myelocytic, in that the former can exist in chronic form without symptoms for years whereas the latter rarely does so Hæmorrhages are absent in glandular fever.

3 *Total leucocytes*—In the acute lymphatic leukæmia of adults the number is often within normal limits and probably rarely exceeds 30,000. In children the figure may be considerably higher A high count in an adult suggests the terminal phase of a more chronic condition. In acute myeloblastic leukæmia the total figure may be considerably higher, but in the fulminating acute form it is usually low In glandular fever the usual number is from 20.000 to 30 000

4. *Type of leucocyte*—Large type lymphocytes are characteristic of acute lymphatic leukæmia and of glandular fever The presence of "smeared nuclei" is very characteristic of the lymphatic type Cases with a mixed count of large lymphocytes and megaloblasts usually terminate as pure myeloblastic. Lambright's oxidase stain is more reliable than Goodpasteur's stain or the Jenner-Giemsa method for distinguishing myeloblasts from large lymphocytes

5 *Red cells*—Reduction in numbers and hæmoglobin is characteristic of both acute types, but is most marked in acute myeloblastic leukæmia. Numerous megaloblasts and macrocytes suggest myeloblastic; they are often present with a comparatively small reduction in numbers of cells; minor abnormalities only, such as normoblasts and poikilocytes—especially if ill-marked in spite of the severe reduction in total numbers—suggest the acute lymphatic In both types the anæmia is rapidly progressive and the prognosis as to duration depends on the red cell count and hæmoglobin rather than the leucocyte count Changes in the numbers of red cells and abnormal red cells are absent in glandular fever

We are indebted to Dr R A. Young and Dr C E Lakin, physicians to the Middlesex Hospital and to Dr. J C R. Braine-Hartnell Dr Allman Powell and Dr F J Lidderdale, of the honorary staff of the Cheltenham General and Eye Hospital for their permission to publish these cases

SULPHUR METABOLISM IN ARTHRITIS DEFORMANS.

BY A P. CAWADIAS O.B E. M D DURH AND PARIS. M R C.P. LOND.

FORMERLY CHIEF OF MEDICAL CLINIC, PARIS UNIVERSITY, BEAUJON HOSPITAL AND SENIOR PHYSICIAN AND LECTURER FOR CLINICAL MEDICINE, EVANGELISMOS HOSPITAL, ATHENS

OF the three known forms of sulphur which are concerned in metabolism—mineral suphates, sulphur lipoids, and protein sulphur—it is the last which is the more important and has been exclusively studied in physiopathology.

The question which first arises is whether these sulphur-containing proteins have a separate metabolic history and a special function differing form that of the other proteins Recent research answers in the affirmative this double question. That the metabolic history is different is shown by the fact that in certain conditions such as inanition, convalescence, various diseases, there is not a parallel catabolism of sulphur-containing proteins, and of proteins not containing sulphur. On the other hand, whereas in the proteins of the food the ratio between sulphur and nitrogen varies between 1 7 and 14 6 : 100 the same ratio in the urine is much more fixed in the neighbourhood of 7 : 100 which shows that the organism does not catabolise all proteins indifferently but that it catabolises the sulphur-containing proteins and the non-sulphur containing proteins, so that the two are excreted in a fairly fixed ratio

That these sulphur-containing proteins have a definite and special function due to the sulfhydryl element has been shown by the works of de Ray Paillade Thunberg, Heffter, and definitely demonstrated by the brilliant researches of Sir F. Gowland Hopkins This last-named author has proved that an organic sulphur compound glutathion, tissue in which endothelial cells were prominent, together with many small thin-walled vessels, the interstices were packed with lymphocytes, no Hassall's corpuscles seen. The marrow in the sternal end of the clavicle and in the manubrium was abundant and bright red. Smears of the marrow showed large numbers of lymphocytes and when stained by Goodpasteur's oxidase method showed very few cells containing granules, nucleated red cells and myelocytes were present in small numbers.

In commenting on this case, we note that the findings agree with those of Still,[9] who says, "Leukæmia in childhood is almost always a lymphatic type . . . the excess of lymphocytes being almost always due mainly to increase of the small lymphocyte." It is noteworthy that the duration of the case was at least nine weeks and it should therefore, strictly speaking, be classified as subacute. This may probably account for the great splenic enlargement and the somewhat high total leucocyte count, though in children both these factors are apt to be more marked in acute cases than they are in adults.

duplicated—and many of them showed degenerative changes which probably obscured the nucleoli, on the whole, they occupied more of the cell body than did the nuclei of the large lymphocytes.

This case contrasts greatly with Case 3, yet both are manifestations of primary myeloblastic leukæmia. In Case 3 the myeloblastic process involved mainly the spleen and glands—as evidenced by their enlargement—and left the erythroblastic tissue of the bone-marrow comparatively untouched, as evidenced by the small reduction in the red cells. In Case 6 the tissue most involved was the more vulnerable bone-marrow with a resulting severe anæmia and an incapacity to recover from any hæmorrhages.

The cause of death in Case 3 was probably renal obstruction, not bone-marrow exhaustion, and the initial prognosis was therefore theoretically better, it is conceivable that if the hæmorrhages could have been arrested the patient might have settled down to a more chronic type of disease.

CASE 7

Date in 1926	Hæmoglobin	Red cells	Colour index	Leucocytes	Polymorphs	Lymphocytes	Mononuclears	Eosinophils	Red cells	Remarks
June 20th	82	4,560,000	0.9	32,900	4.6	95.0	0.4	Nil	Nil abnormal	Predominant large lymphocyte. Occasional questionable myeloblast present

CASE 6. *Acute Myeloblastic Leukæmia.*—A man, aged 26, was admitted on March 4th, 1926, to the Cheltenham General Hospital under Dr. J. Allman Powell. The first symptom, epistaxis, had appeared two weeks before his death.

History.—The patient had been in good health and followed his occupation (clerk) until at 3 A.M. his nose began to bleed. At the Cheltenham Eye, Ear and Throat Hospital the bleeding was traced to two dilated venules on the nasal septum, but despite all possible measures, blood continued to ooze from the nose thus adding to the already extreme anæmia. Seven days later he developed a right-sided tonsillitis with a temperature of 103°, and was then transferred to the General Hospital. He was extremely pale, no gross abnormality was present in the thorax or abdomen, and the spleen was not enlarged. There were a few shotty glands in the inguinal region and one external to the inflamed right tonsil. A blood examination three days after admission showed hæmoglobin, 13 per cent. (approximately), red cells, 730,000, leucocytes, 9440, polymorphs, 4.7 per cent., myeloblasts, 70.3 per cent., myelocytes, 7.0 per cent., promyelocytes, 0.3 per cent., lymphocytes, 17.4 per cent. mononuclears, 3 per cent., 2.3 megaloblasts and 2.7 normoblasts per 100 leucocytes. Marked anisocytosis.

The myeloblasts bore the usual close resemblance to large lymphocytes, and nucleoli were not evident in many of them, but their identity was easily confirmed by Lambright's stain, which showed 83.2 per cent. of leucocytes contained oxidase granules—a figure remarkably close to the 82.3 obtained for "true bone-marrow cells" in the Leishman-stained film.

Death occurred the next day. There was no epistaxis during the last few days of life, but the patient frequently vomited blood—mostly black, occasionally small amounts of red blood.

Post-mortem of the abdominal viscera showed no enlargement of glands or spleen, there was extreme pallor of the viscera especially the kidneys, but sections of the latter showed *no* infiltration with myeloblasts. The stomach contained "coffee ground material."

We would emphasise the definite assistance given by Lambright's stain. On comparing the myeloblasts with the large lymphocytes of Cases 4 and 5, the former showed a smaller average size and a much less clear and darker staining cell cytoplasm with no azur granules. The myeloblastic nuclei were variable in shape—round, oval, reniform, and sometimes

CASE 7. *Glandular Fever.*—A married woman, aged 20, with one child came under the care of Dr. A. F. R. Conder on May 24th, 1926, complaining of sore-throat. Both tonsils were enlarged and reddened and small discrete glands were present in the neck. While under treatment for the sore throat she developed a pale, measly rash on the abdomen, chest, and back, and some readily palpable occipital glands. She felt perfectly well. On June 15th her temperature was 99.4° F., pulse 80. The following day there was no change, but on the 17th she felt ill, her evening temperature was 103° and she was perspiring freely, 24 hours later the glandular swellings had increased, some being as large as hazel nuts. Her temperature was 103°, pulse 116. A blood examination performed on June 19th showed leucocytes, 22,900, polymorphonuclears, 10.8, lymphocytes, 78.8, large mononuclears, 10.0, eosinophils, 0.4, no nucleated red cells, no poikilocytosis or anisocytosis, blood-platelets numerous, all grades from small to large lymphocytes present, the latter predominating. The blood picture suggested leukæmia, but in view of the absence of any indications of red cell destruction, a definite diagnosis was not made pending further examinations. On June 20th the rash had disappeared, leaving deep staining all over the abdomen. The patient's condition was distinctly worse, she was very weak and almost unable to sit up in bed, she vomited twice and complained of abdominal pain. There was no further enlargement of the cervical glands, but the axillary and left inguinal glands were easily palpable. There was no enlargement of the liver or spleen. (See table for blood count.)

The next day there was slight improvement in the general condition and a further blood count was performed. Dr. Letheby Tidy saw the patient on June 23rd and made a diagnosis of glandular fever, in view of the steady improvement in the general condition and the absence of changes in the red cells. By June 30th the patient was much better. The evening temperature was only a little above normal but nocturnal perspiration was still present and the spleen easily palpable. By July 5th the patient was well enough to get out of bed. The spleen could no longer be felt, but the liver projected 1½ inches below the ribs. A blood count was performed. On July 31st the patient expressed herself as quite recovered, another blood count was performed.

The clinical features of this case which tended to simulate acute lymphatic leukæmia, were fever, malaise, and rapid enlargement of glands and spleen, the difference was the absence of hæmorrhages. The hæmatological finding common to the two diseases

The following are certain results from my patients:—

Kar.	Ethereal sulphates in 24 hours urine	0·26
Ts.		0·24
Zach.		0·41
Proc		0·87
Pan.		0·60
Ko's.		0·58
Pap		0·50

This slight excess of sulphoconjugation which means excess of production of aromatic products, cannot be attributed to intestinal putrefactions because my patients did not show any clinical or coprological sign of abnormal intestinal digestion, but may be attributed either to a certain loss in chondroitin sulphuric acid, which is an important constituent of cartilage, or to an abnormal protein metabolism. Although the question is very much discussed, we have the authority of Folin for admitting that aromatic products, except indol, are not only derived from intestinal putrefactions or from putrefactions of proteins in a focus of abscess or gangrene but that they may also be derived from an abnormal protein metabolism. In one patient the quantity of ethereal sulphates decreased distinctly after treatment with colloidal sulphur, and this coincided with a complete recovery.

General Conclusions.

In arthritis deformans sulphur oxidation is not disturbed, sulphoconjugation is in some cases slightly increased, but there is a definite inefficiency of thiopexy. In the light of these researches we can consider that the external causes of rheumatoid arthritis—microbes toxins, or even physical conditions, such as dampness—act first on certain regulators of metabolism and principally of sulphur metabolism, regulators which are more or less predisposed. As a result of the involvement of these organs metabolic troubles and especially sulphur metabolic troubles are elicited, and it is probable that the articular lesions are the ultimate result of these metabolic troubles.

The results of sulphur treatment demonstrated by clinical experience corroborate that conception, and I have myself seen in some patients an improvement of the thiopexic function under the influence of colloidal sulphur treatment.

THE LATE DR. JOHN W. PINDER.—Dr. John William Pinder, who died at Horsforth, near Leeds on June 1st at the age of 78, was well known in the district having practised there from 1870 until his retirement some years ago. A native of Horsforth and the son of a local practitioner he studied at the Leeds Medical School qualifying L.S.A. Lond. in 1869 and M.R C S. Eng. in 1870 From 1867–69 he was assistant resident medical officer at the Leeds General Infirmary. A keen politician, he was also interested in agriculture and devoted his leisure to farming. He leaves four sons and three daughters.

RETINAL PETECHIASIS.

A CURABLE CONDITION CAUSING BLINDNESS

ITS DESCRIPTION AND ITS BEARING ON SIMILAR LESIONS ELSEWHERE IN THE BODY.

BY H MORELAND McCREA, O.B.E, M.D. R U.I.

(WITH COLOURED PLATE)

ON Jan 14th, 1927, I read a paper before the Ophthalmological Section of the Royal Society of Medicine on Retinal Petechiasis. In that communication I drew attention to a type of hæmorrhage in the retina causing blindness the precise nature of which had not hitherto been recognised, and in consequence its treatment had not been conducted on proper lines. The lamentable result of this incorrect diagnosis and treatment is that a number of patients are condemned to a state of blindness from which they could have been saved I gave to this state the name retinal petechiasis and I showed that the extravasated blood had exuded from unruptured vessel walls.

The circulatory disturbances in the retina have hitherto been classified under two headings, to which I now add a third, as follows:—

1. Retinal hæmorrhage, due to rupture of the vessel walls which occurs in elderly people whose blood-vessels show marked degenerative changes and whose blood pressures (particularly the diastolic) are almost invariably high. It is recognised that little or no treatment can benefit this condition.

2. Retinal thrombosis which leads to destruction of retinal tissue by hæmorrhagic extravasation, and which is also associated with blood vascular degenerative changes: treatment in this state also is of little avail.

3 There is, however, the third type which I am confident should be isolated as definite clinical entity, and for which I suggested the name of retinal petechiasis. (1) The clinical history and definite ophthalmological appearances; (2) the prognosis; and (3) the response to treatment of retinal petechiasis are all three sharply defined from those of retinal hæmorrhage.

The difference between the clinical history of retinal petechiasis and that of hæmorrhage is striking My experience shows that the high blood pressure which accompanies retinal hæmorrhage is not a factor in retinal petechiasis Retinal petechiasis may occur at any time from middle age onwards The youngest patient in my series was a female aged 40 years and it may occur in advanced age. The age of a patient should be no deterrent to investigation and treatment. Two of my cases amply illustrate this important point. The age of the one was 80 and the age of the other was 83, the former patient after treatment, but not before, was able to read the type of an ordinary novel, and the vision of the latter improved to 6/12 part and Sn. 4. Both these patients were referred to me by their ophthalmic surgeons as having very poor vision. Again, in retinal hæmorrhage there are signs elsewhere of vascular degeneration but in petechiasis there may be no such evidence. The urine in my cases of retinal petechiasis, with one exception, showed no abnormality, and there was no case where polyuria was a symptom.

Pathology.

From a pathological view it is not a true retinal hæmorrhage, but differs from it in several important respects. In retinal petechiasis the blood-vessel wall is not ruptured and blood is only exuded from a vessel with intact walls. This is well seen in the coloured plate (Figs. 1, 2, 3) where intact blood-vessels can be seen traversing the exudate.

The distinction I make between retinal petechiasis and retinal hæmorrhage may be compared to the rusty sputum of pneumonia and to the hæmaturia in exists in our cells and plays a very important rôle in all processes of oxidation and reduction.

It seems, therefore, interesting to study in the course of various morbid conditions troubles of sulphur metabolism, and I think that this study will give especially good results in rheumatoid arthritis in which sulphur treatment has been clinically demonstrated as very effective

The Normal Processes of Sulphur Metabolism.

We can distinguish three phases in the normal sulphur metabolism In the first phase, sulphur is dislocated from its protein compound under the form of imperfectly oxidised or neutral sulphur (cystine, cysteine, oxyproteic acid, &c) About 20 per cent of this neutral sulphur is not subjected to any further modification and is eliminated as such with the urine, and to a small extent with the fæces.

The greatest part of the neutral sulphur enters into a second metabolic phase and is thus subjected to a further modification, the oxidation It is thus transformed into completely oxidised sulphur, that is sulphuric acid which combines with certain alkaline bases and is eliminated with the urine in the form of mineral sulphates

A small portion of the completely oxidised sulphur is not eliminated under the form of mineral sulphates, but enters into a third metabolic phase, that of sulphoconjugation It combines with certain toxic products derived either from putrefaction or, in general, from an abnormal metabolism of proteins, and, thanks to that combination, renders these products non-toxic By combining with the so-called aromatic products derived from putrefaction of proteins in the intestine or from protein destruction in a focus of suppuration in the body or even from an abnormal metabolism of food and cellular proteins, it transforms these toxic aromatic products into non-toxic ethereal sulphates which are eliminated with the urine, and, by combining with the cyanates—also products of protein catabolism—it transforms them into the less toxic compounds sulfocyanates (L C Maillard admits that this sulfoconjugation occurs before the phase of sulphur oxidation)

This general metabolic progression is the same for the exogenous as well as for the endogenous sulphur-containing proteins, except for the fact that endogenous sulphur proteins stop for the greatest part in the phase of neutral sulphur Normally, in the adult, there is a perfect sulphur equilibrium. Sulphur catabolised and eliminated on account of the normal wear and tear of our cells is replaced by exogenous sulphur. The name of Thiopexy is given to that special metabolic function of the organism through which the sulphur equilibrium is maintained. Thiopexy, sulphur oxidation, and sulphur conjugation, are the three metabolic functions of the organism regarding the sulphur The organs which regulate this sulphur metabolism are not well known, but it is very probable —as Prof Albert Robin and Prof Loeper of Paris admit—that the liver plays a great rôle Certain incomplete experimental data show also the influence of the thyroid

Thiopexy in Arthritis Deformans

The ideal method for the study of the function of thiopexy would consist in determining the quantity of sulphur contained in the ingesta and the quantity of sulphur excreted with the urine and the fæces, and to find out if there is an equilibrium, a *positive or* a negative balance

We have adopted a more simple but more clinical method In patients submitted to a fixed diet containing 1 g of protein per kilo of weight of the patient, we determine the total sulphur by the Salkowski method, and the total nitrogen by the Kjehldal technique The ratio total sulphur total nitrogen indicates the condition of the function of thiopexy. It may be called the thiopexy index. Normally, under such conditions, an adult excretes about 2 50 of total SO_3 and the ratio total sulphur to total nitrogen is about 1 · 7 up to 1 . 10. If in that ratio the sulphur element is increased, it means that there is an increased catabolism of the sulphur-containing proteins, a loss of sulphur, or in other words a deficient thiopexy. We cannot take into consideration the cases in which the total sulphur excretion is increased, but the ratio total sulphur total nitrogen remains normal Under these circumstances, we have to do, perhaps, with a general increased catabolism of protein, but not with a special increased catabolism of sulphur-containing proteins

The greatest difficulty in the interpretation of this sulphur nitrogen coefficient arises because various authors do not agree as to its average normal value This disagreement is due to differences in technique, not only concerning the chemical analysis but concerning also the diet to which the patient is submitted That is why we have taken into consideration only extreme variations from the normal average. Even if we consider only these great variations, we find in rheumatoid arthritis an increase of sulphur catabolism, that is a deficient thiopexic function Among various determinations, (*made by the Salkowski* method) I give the following examples —

Kar	Total urine SO_3 of 24 hours	3 12	ratio S/N	1 3
Proc		3 50	,,	1 3
Pan		3 72	,,	1 3 5
Kots		4 20	,,	1 4 5
Pap		3 60	,,	1 2 5

Goldthwaite, Painter, and Osgood have found in one case of hypertrophic arthritis an increased thiopexy—that is, a retention of sulphur It is probable that this indicated a defensive process I have not met with such a retention in my numerous determinations

Sulphur Oxidation in Arthritis Deformans

The diagnosis of the condition of sulphur oxidation can be made by determining separately, by the method of Salkowski, the neutral sulphur and the total sulphur, and fixing the ratio neutral sulphur total sulphur This ratio which Albert Robin calls "coefficient of sulphur oxidation" is about 10 to 20 per cent The relative increase of neutral sulphur does not indicate only the diminished capacity of the organism to oxidise sulphur As Folin has shown neutral sulphur in urine represents principally the catabolism of the endogenous sulphur-containing proteins A ratio therefore neutral sulphur—total sulphur higher than 20 100 does not indicate necessarily a defect in sulphur oxidation, but may also be a sign of increased endogenous sulphur catabolism

The following are the results taken at random from determinations in patients with arthritis deformans —

Kar	Neutral S towards total S	17 per cent.
Ts		21 ,,
Zach		14 ,,
Proc		18 ,,
Pan		24 ,,
Kots		16 ,,
Pap		20 ,,

Bearing in mind Folin's criticism on the interpretation of this sulphur oxidation coefficient and the fact that in my determinations I have not found great variations from the highest limits of the normal standard, I think we cannot conclude to any definite trouble of sulfo-oxidation in arthritis deformans These conclusions correct those I gave in my preliminary note two years ago when I had only a small number of determinations and had not taken into consideration the works of Folin on this subject

Sulphoconjugation in Arthritis Deformans.

The diagnosis of sulphoconjugation is made by determining the quantity of ethereal sulphates in the 24 hours urine. My determinations were made by the Salkowski method Here also we find divergent opinions as to the normal standard C Tollen finds an average of 0 18 of ethereal sulphates SO_3 in 24 hours urine We can *consider as slightly abnormal* the quantities above 0 40 and as definitely abnormal the quantities above 0 60 In most cases—but not in all—of arthritis deformans the excretion of ethereal sulphates is slightly above the normal standard

The following are certain results from my patients :—

Kar	Ethereal sulphates in 24 hours urine	0 26
Ts		0 24
Zach.		0 41
Proc.		0 87
Pan.		0 60
Kots		0 58
Pap		0 50

This slight excess of sulphoconjugation which means excess of production of aromatic products, cannot be attributed to intestinal putrefactions, because my patients did not show any clinical or coprological sign of abnormal intestinal digestion, but may be attributed either to a certain loss in chondroitin sulphuric acid, which is an important constituent of cartilage, or to an abnormal protein metabolism Although the question is very much discussed we have the authority of Folin for admitting that aromatic products, except indol, are not only derived from intestinal putrefactions or from putrefactions of proteins in a focus of abscess or gangrene but that they may also be derived from an abnormal protein metabolism In one patient the quantity of ethereal sulphates decreased distinctly after treatment with colloidal sulphur, and this coincided with a complete recovery.

General Conclusions

In arthritis deformans sulphur oxidation is not disturbed, sulphoconjugation is in some cases slightly increased. but there is a definite inefficiency of thiopexy In the light of these researches we can consider that the external causes of rheumatoid arthritis—microbes toxins, or even physical conditions. such as dampness—act first on certain regulators of metabolism and principally of sulphur metabolism, regulators which are more or less predisposed As a result of the involvement of these organs metabolic troubles and especially sulphur metabolic troubles are elicited, and it is probable that the articular lesions are the ultimate result of these metabolic troubles

The results of sulphur treatment demonstrated by clinical experience corroborate that conception, and I have myself seen in some patients an improvement of the thiopexic function under the influence of colloidal sulphur treatment

RETINAL PETECHIASIS.

A CURABLE CONDITION CAUSING BLINDNESS

ITS DESCRIPTION AND ITS BEARING ON SIMILAR LESIONS ELSEWHERE IN THE BODY.

BY H MORELAND McCREA, O B E, M.D R U I

(WITH COLOURED PLATE)

ON Jan 14th. 1927, I read a paper before the Ophthalmological Section of the Royal Society of Medicine on Retinal Petechiasis In that communication I drew attention to a type of hæmorrhage in the retina causing blindness the precise nature of which had not hitherto been recognised, and in consequence its treatment had not been conducted on proper lines The lamentable result of this incorrect diagnosis and treatment is that a number of patients are condemned to a state of blindness from which they could have been saved I gave to this state the name retinal petechiasis and I showed that the extravasated blood had exuded from unruptured vessel walls

The circulatory disturbances in the retina have hitherto been classified under two headings, to which I now add a third, as follows.—

1 Retinal hæmorrhage. due to rupture of the vessel walls which occurs in elderly people whose blood-vessels show marked degenerative changes and whose blood pressures (particularly the diastolic) are almost invariably high It is recognised that little or no treatment can benefit this condition

2. Retinal thrombosis, which leads to destruction of retinal tissue by hæmorrhagic extravasation, and which is also associated with blood vascular degenerative changes; treatment in this state also is of little avail.

3. There is however, the third type which I am confident should be isolated as definite clinical entity, and for which I suggested the name of retinal petechiasis (1) The clinical history and definite ophthalmological appearances; (2) the prognosis; and (3) the response to treatment of retinal petechiasis are all three sharply defined from those of retinal hæmorrhage

The difference between the clinical history of retinal petechiasis and that of hæmorrhage is striking My experience shows that the high blood pressure which accompanies retinal hæmorrhage is not a factor in retinal petechiasis Retinal petechiasis may occur at any time from middle age onwards The youngest patient in my series was a female aged 40 years, and it may occur in advanced age. The age of a patient should be no deterrent to investigation and treatment. Two of my cases amply illustrate this important point. The age of the one was 80 and the age of the other was 83, the former patient after treatment, but not before, was able to read the type of an ordinary novel, and the vision of the latter improved to 6/12 part and Sn 4. Both these patients were referred to me by their ophthalmic surgeons as having very poor vision Again, in retinal hæmorrhage there are signs elsewhere of vascular degeneration. but in petechiasis there may be no such evidence The urine in my cases of retinal petechiasis, with one exception. showed no abnormality, and there was no case where polyuria was a symptom.

Pathology.

From a pathological view it is not a true retinal hæmorrhage, but differs from it in several important respects In retinal petechiasis the blood-vessel wall is not ruptured and blood is only exuded from a vessel with intact walls This is well seen in the coloured plate (Figs 1, 2, 3) where intact blood-vessels can be seen traversing the exudate.

The distinction I make between retinal petechiasis and retinal hæmorrhage may be compared to the rusty sputum of pneumonia and to the hæmaturia in exists in our cells and plays a very important rôle in all processes of oxidation and reduction.

It seems, therefore, interesting to study in the course of various morbid conditions troubles of sulphur metabolism, and I think that this study will give especially good results in rheumatoid arthritis in which sulphur treatment has been clinically demonstrated as very effective

The Normal Processes of Sulphur Metabolism.

We can distinguish three phases in the normal sulphur metabolism In the first phase, sulphur is dislocated from its protein compound under the form of imperfectly oxidised or neutral sulphur (cystine, cysteine, oxyproteic acid, &c) About 20 per cent of this neutral sulphur is not subjected to any further modification and is eliminated as such with the urine, and to a small extent with the fæces

The greatest part of the neutral sulphur enters into a second metabolic phase and is thus subjected to a further modification, the oxidation It is thus transformed into completely oxidised sulphur, that is sulphuric acid which combines with certain alkaline bases and is eliminated with the urine in the form of *mineral sulphates*

A small portion of the completely oxidised sulphur is not eliminated under the form of mineral sulphates, but enters into a third metabolic phase, that of sulphoconjugation It combines with certain toxic products derived either from putrefaction or, in general, from an abnormal metabolism of proteins, and, thanks to that combination, renders these products non-toxic By combining with the so-called aromatic products derived from putrefaction of proteins in the intestine or from protein destruction in a focus of suppuration in the body or even from an abnormal metabolism of food and cellular proteins, it transforms these toxic aromatic products into non-toxic ethereal sulphates which are eliminated with the urine, and, by combining with the cyanates—also products of protein catabolism—it transforms them into the less toxic compounds sulfocyanates (L C Maillard admits that this sulfoconjugation occurs before the phase of sulphur oxidation)

This general metabolic progression is the same for the exogenous as well as for the endogenous sulphur-containing proteins, except for the fact that endogenous sulphur proteins stop for the greatest part in the phase of neutral sulphur Normally, in the adult, there is a perfect sulphur equilibrium. Sulphur catabolised and eliminated on account of the normal wear and tear of our cells is replaced by exogenous sulphur. The name of Thiopexy is given to that special metabolic function of the organism through which the sulphur equilibrium is maintained. Thiopexy, sulphur oxidation, and sulphur conjugation, are the three metabolic functions of the organism regarding the sulphur The organs which regulate this sulphur metabolism are not well known, but it is very probable —as Prof Albert Robin and Prof. Loeper of Paris admit—that the liver plays a great rôle Certain incomplete experimental data show also the influence of the thyroid

Thiopexy in Arthritis Deformans

The ideal method for the study of the function of thiopexy would consist in determining the quantity of sulphur contained in the ingesta and the quantity of sulphur excreted with the urine and the fæces, and to find out if there is an equilibrium, a positive or a negative balance

We have adopted a more simple but more clinical method In patients submitted to a fixed diet containing 1 g of protein per kilo of weight of the patient, we determine the total sulphur by the Salkowski method, and the total nitrogen by the Kjehldal technique The ratio total sulphur total nitrogen indicates the condition of the function of thiopexy. It may be called the thiopexy index Normally, under such conditions, an adult excretes about 2 50 of total SO_3 and the ratio total sulphur to total nitrogen is about 1 7 up to 1 10. If in that ratio the sulphur element is increased, it means that there is an increased catabolism of the sulphur-containing proteins, a loss of sulphur, or in other words a deficient thiopexy. We cannot take into consideration the cases in which the total sulphur excretion is increased, but the ratio total sulphur total nitrogen remains normal Under these circumstances, we have to do, perhaps, with a general increased catabolism of protein, but not with a special increased catabolism of sulphur-containing proteins

The greatest difficulty in the interpretation of this sulphur : nitrogen coefficient arises because various authors do not agree as to its average normal value This disagreement is due to differences in technique, not only concerning the chemical analysis but concerning also the diet to which the patient is submitted That is why we have taken into consideration only extreme variations from the normal average Even if we consider only these great variations, we find in rheumatoid arthritis an increase of sulphur catabolism, that is a deficient thiopexic function Among various determinations, (made by the Salkowski method) I give the following examples .—

Kar	Total urine SO_3 of 24 hours	3 12	ratio S/N	1 3
Proc		3 50	,,	1 3
Pan		3 72	,,	1 3 5
Kots		4 20	,,	1 4 5
Pap		3 60	,,	1 2 5

Goldthwaite, Painter, and Osgood have found in one case of hypertrophic arthritis an increased thiopexy—that is, a retention of sulphur. It is probable that this indicated a defensive process I have not met with such a retention in my numerous determinations

Sulphur Oxidation in Arthritis Deformans

The diagnosis of the condition of sulphur oxidation can be made by determining separately, by the method of Salkowski, the neutral sulphur and the total sulphur, and fixing the ratio neutral sulphur total sulphur This ratio which Albert Robin calls "coefficient of sulphur oxidation" is about 10 to 20 per cent The relative increase of neutral sulphur does not indicate only the diminished capacity of the organism to oxidise sulphur As Folin has shown neutral sulphur in urine represents principally the catabolism of the endogenous sulphur-containing proteins A ratio therefore neutral sulphur—total sulphur higher than 20 · 100 does not indicate necessarily a defect in sulphur oxidation, but may also be a sign of increased endogenous sulphur catabolism

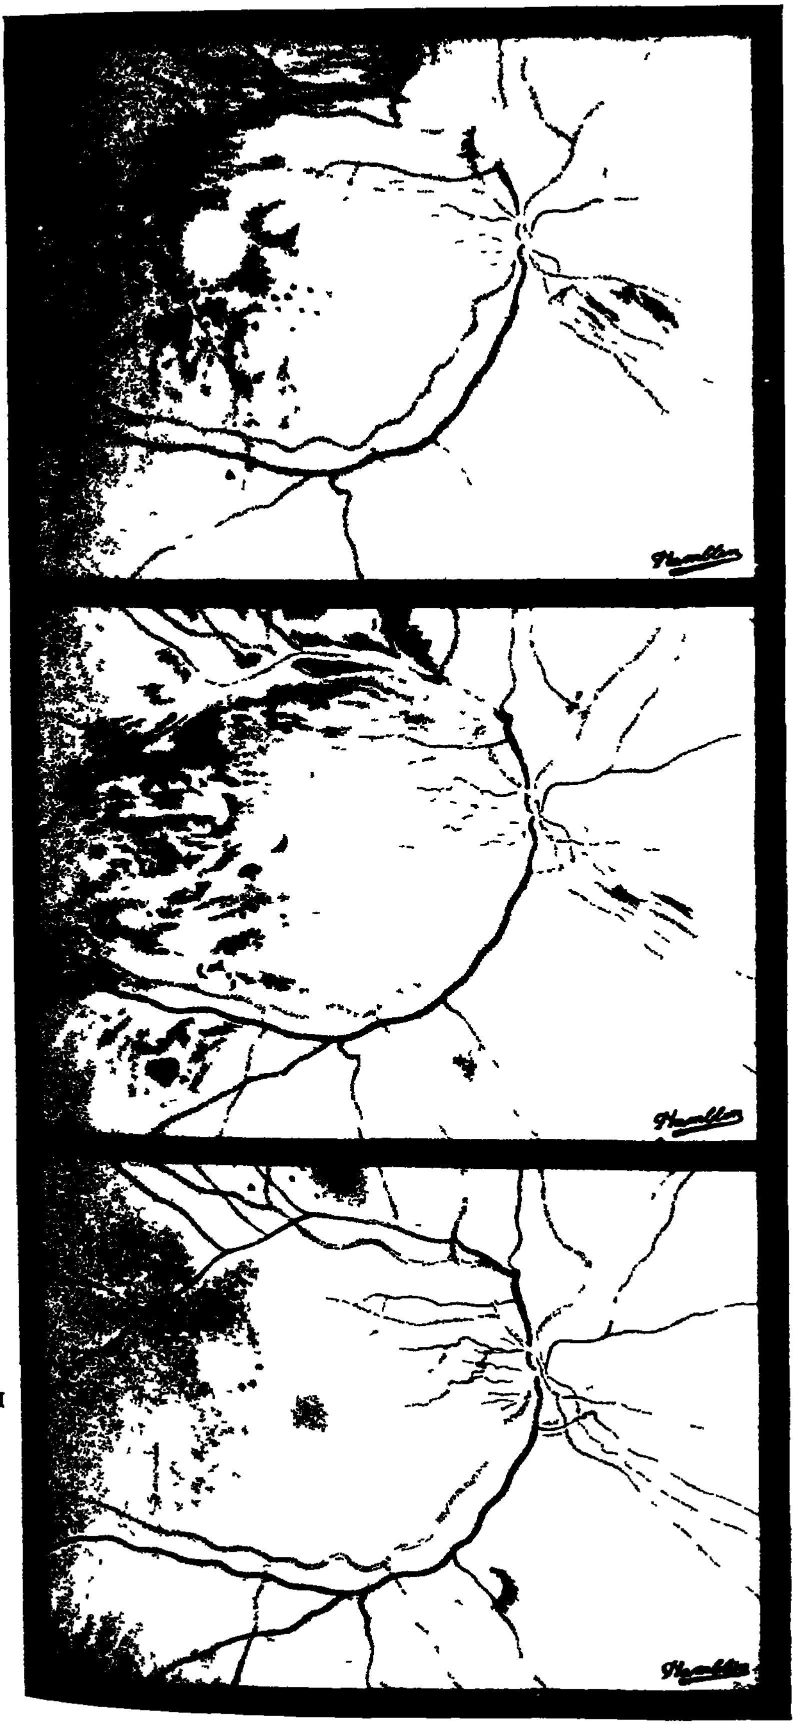
The following are the results taken at random from determinations in patients with arthritis deformans :—

Kar	Neutral S towards total S	17	per cent
Ts		21	,,
Zach		14	,,
Proc		18	,,
Pan.		24	,,
Kots		16	,,
Pap		20	,,

Bearing in mind Folin's criticism on the interpretation of this sulphur oxidation coefficient and the fact that in my determinations I have not found great variations from the highest limits of the normal standard, I think we cannot conclude to any definite trouble of sulfo-oxidation in arthritis deformans These conclusions correct those I gave in my preliminary note two years ago when I had only a small number of determinations and had not taken into consideration the works of Folin on this subject

Sulphoconjugation in Arthritis Deformans

The diagnosis of sulphoconjugation is made by determining the quantity of ethereal sulphates in the 24 hours urine My determinations were made by the Salkowski method Here also we find divergent opinions as to the normal standard C Tollen finds an average of 0 18 of ethereal sulphates SO_3 in 24 hours urine We can consider as slightly abnormal the quantities above 0 40 and as definitely abnormal the quantities above 0 60 In most cases—but not in all—of arthritis deformans the excretion of ethereal sulphates is slightly above the normal standard



THESE figures illustrate a typical case of retinal petechiasis

The patient was a man, aged 49, who a month previously had suddenly lost the sight of the right eye The case was referred to me with the report of a hæmorrhage in the region of the macula of the right eye with a cloudy vitreous vision 6/60 My general examination showed a normal cardiovascular system, a B P 148–86, no albumin or polyuria, a very septic mouth with pus from two stumps of lower wisdoms which had been left two years ago after an attempt at their extraction had been abandoned There was also a very septic but intact upper left molar and two very septic tonsils

FIG I is an exact drawing of the state of the retina at this time. Note (1) the exudates in the region of the macula and due south of the disc, (2) the vessels running north-west of the disc passing through the exudate, and (3) the linear splashes due east of the disc.

The teeth were at once extracted

FIG II depicts the same area three weeks later, fresh splashes had occurred, although the vision had improved to 6/36 It was then decided to enucleate the tonsils Three weeks after this operation was performed the vitreous was clear, the splashes had almost entirely disappeared, and vision was 6/9 Sn. 4.

FIG III depicts the same area nearly two months after enucleation of the tonsils The vitreous was clear and vision 6/6 and Sn 1 c. glasses The exudate has almost completely disappeared

In comparing the states of blood-vessels in Figs I, II, and III., the vessels can be seen passing through the exudate blood In Fig. III the vessel wall is intact, although there is still some exudate around it, showing that the vessel has not ruptured

DR. H. MORELAND McCREA. RETINAL PETECHIASIS.

acute nephritis Although blood appears in the sputum and urine, respectively, it has escaped from the blood-vessels by exudation and not by rupture of the walls When walking along the banks of a brimming stream one can often notice little patches of well-grown grass in ground so sodden with moisture that water oozes out with the pressure of every footstep The stream has not burst its banks; its water has exuded into the neighbouring soil

Retinal petechiasis is produced in an analogous way There is an exudation of blood without rupture of a blood-vessel, and it is a process that has quite a different pathology and significance to retinal hæmorrhage that is a result of rupture of a blood-vessel wall It is impossible to speak dogmatically of the pathology of retinal petechiasis because so far as I know no opportunity for pathological examination has been possible other than that afforded by ophthalmoscopic means, which show definite and characteristic appearances

In a well-marked case the retina appears bespattered with blood-stained mud (see Figs 1 and 2) In severe cases these splashes may be confluent and the vitreous may be cloudy The appearance then looks as if it were a true hæmorrhage In severe and mild cases *alike, however, these splashes have no relationship to* ruptured blood-vessels, and in Figs 2 and 3 intact blood-vessels may be seen to traverse the exudation

Keogh, of Copenhagen, has shown that "when the capillary walls are subjected to stimulation the response may be in the nature of a contraction or relaxation and also that with relaxation they may become increasingly permeable to the constituents of the blood plasma until when fully dilated they fail altogether to retain them Toxins circulating in the blood can act as stimulus to produce this relaxation" It is my belief that splashes in retinal petechiasis are produced in this way That similar lesions may occur elsewhere in the body from a similar causation is a necessary corollary, and this matter will be discussed later

If the assumption is correct that retinal petechiasis can be produced in this way one should be able first, to discover sources of infection, second, one should be able to remedy retinal petechiasis by the removal of these sources, third, a recurrence of the septic trouble should give rise to fresh manifestations in the retina, and fourth, similar lesions which can be seen elsewhere than in the retina and where direct visibility is also possible, the urinary bladder for example, these should also be subject to the above conditions

Clinical Conditions.

I will now proceed to adduce clinical instances which fulfil these conditions

(1) *Sources of Infection*—Fifteen cases have been reported by me in full and in all of them a definite focus of infection was discovered, and in some two or more foci were detected Concerning the site of these focal infections the teeth, the tonsils, the accessory sinuses of the nasal cavities, the ethmoid, and the urinary tract have been discovered in my cases, either respectively or collectively to be responsible for retinal petechiasis

Good and rapid results have followed the removal of focal sepsis Infected teeth were extracted, septic tonsils enucleated, and sinuses treated In those cases in which operation was contraindicated, as in sepsis of the urinary tract, vaccines were employed and medicines were given, and the results were eminently satisfactory

(2) Out of the 15 cases marked *improvement in vision* rapidly followed treatment in 10, moderate improvement in 2, no improvement with relapse in 2, and 1 case was not seen again In the case in which improvement was marked the cloudy vitreous became clear very rapidly and within a week there was in most cases a marked improvement in vision, the best improvement being 6/60 to 6/6 and Sn 14 to Sn 1 (It has been suggested that the early rapid improvement is due to the disappearance of œdema in the macular region) It will be agreed that this answers the second condition that the removal of the septic focus arrests petechiasis in the retina

(3) *Recurrence*—The recurrence of splashes in the retina resulting from the recurrence of the original septic trouble is, perhaps, the best proof of my contention In three cases I can supply this necessary evidence In one of them fresh splashes in the retina occurred with a marked deterioration in vision, after an exacerbation of ethmoidal sepsis of long standing and improvement resulted again immediately the sepsis was treated

In the second case, one of tooth sepsis, a recurrence of failing vision led to the re-examination of the patient and the left tonsil was found to be very septic, although throat specialists had formerly passed both tonsils as normal It was impossible to operate in this case; the tonsil was, therefore, treated locally and a vaccine was also administered The improvement was not to the extent one would have hoped, but it was quite definite The third case was first referred to me six years previously for "hæmorrhage" in the right eye and deterioration of vision to 6/60. On examination at that time I failed to detect buried tonsils, as it was not my custom then to retract the anterior pillar of the fauces in order to make a proper examination She returned six months ago with hæmorrhage in the left eye, and then I found by retracting the pillars very septic buried tonsils The vision in this eye was down to 6/60 and the vitreous was cloudy The tonsils were enucleated at once and in four weeks the vision in the left eye was 6/6 c glasses She returned again four months later and the vision again was down to 6/60 and the vitreous was again cloudy A careful search was again made for sepsis No focus was found but a catheter specimen taken by myself with extreme caution showed at the end of 24 hours a heavy growth of streptococcus in pure culture in the urine This case is now under treatment, and has already shown marked improvement. These recurrences are distressing but serve to prove my contention, and they point to the advisability of keeping a watchful eye on cases supposed to be cured

(4) *Similar lesions* elsewhere in the body I am not in a position to supply evidence in support of the fourth condition—namely, that similar states should be found elsewhere in the body as a result of similar pathological conditions However, Kidd has found and reported on a case of a similar state in the bladder to which reference will later be made

I have said enough to prove that retinal petechiasis is an important clinical entity which should occupy a position of its own and should not be classified any longer under the heading of retinal hæmorrhage The reason prompting me to prove that retinal petechiasis is a clinical entity is that in my opinion a type of blindness due to this pathological condition exists and is curable, but so long as it remains amongst the group of hæmorrhages of the retina it must unfortunately remain amongst the class of incurables.

THE POSSIBILITY OF A HÆMORRHAGIC STATE ELSEWHERE BEING A CONDITION SIMILAR TO RETINAL PETECHIASIS

While writing this paper concerning petechiasis as it appears in the retina I was aware that it may also be occurring at the same time, either with or without retinal changes, in other internal or external surfaces of the body, and that the retinal changes might be only a local expression of a state of affairs which probably had a wider distribution

There is no doubt that the careful study of this state opens up an entirely new vista and leads one into a new realm of possibilities in diagnosis and treatment of certain states elsewhere in the body where hæmorrhage occurs Kidd touched on the subject as far back as 1913 in a contribution to the *Annals of Surgery* entitled Purpura of the Bladder The case described by him was one of hæmaturia which he considered was due to purpura of the bladder, secondary to a bacterial infection of the tonsil The appearance of the bladder by cystoscopic examination, while the hæmaturia persisted, he described as follows —

> "The bladder wall for the greater part appeared pale and healthy, but scattered irregularly over fundus and trigone were seen patches of submucous hæmorrhages varying in size from a pin's head to a sixpence The patches were of all shapes and sizes, some linear, some stellate The greater number were scattered over the fundus There was no ulceration "

A fortnight later, after the hæmaturia had ceased, cystoscopic examination revealed no evidence of hæmorrhage in the mucous membrane of the bladder There is a striking similarity in the appearances at the first examination of the bladder to those described by me in the retina (see Figs 1, 2) The similarity of their disappearance is also complete The fact that Kidd has found a state in the bladder similar to that I have described in the retina and that he considers it to be due to a precisely similar cause —namely, a septic focus elsewhere in the body—opens up an important field of inquiry. Here are two situations in the body where it is possible to observe vessels and to watch their pathological changes and in both places petechiasis has been described by different observers, causing in one the splashes in the retina associated with cloudiness in the vitreous and in the other a similar lesion in the bladder mucosa with hæmaturia

I believe it is true that the retinal changes I have described and also the changes in the bladder described by Kidd are due to the presence of a septic focus elsewhere in the body If this be so, then the larger proposition is also highly probable, that many hæmorrhages from other mucous membranes of the body may also be due to petechiasis from the same causes—namely, septic foci elsewhere in the body For example, not infrequently operations are performed on the abdomen for hæmatemesis or melæna in the belief that ulcers of the stomach or duodenum will be demonstrated, yet none have been discovered

Two cases occurring in my own experience illustrate this point They had symptoms of duodenal trouble with melæna In the first, at the operation small petechial hæmorrhages were visible in the second part of the duodenum without definite evidence of ulceration; in the second, a similar state was found by the surgeon who was satisfied there was also a thickening in the first part of the duodenum which he considered to be an ulcer Some time later old chronic septic antra in the first case and very septic tonsils in the second were dealt with They are now quite well, but the cure of their digestive trouble was completed only after the removal of the septic foci If septic foci had been discovered and treated earlier in these cases the hæmorrhages might have been cured without the performance of abdominal operations

Further, it is conceivable that blood corpuscles which have exuded from a capillary may be so great in proportion that they may rupture the continuity of an epithelial surface or render its nutrition so feeble that gastric duodenal or intestinal secretions may act upon it and produce ulceration Therefore my observations in the retina in conjunction with Kidd's observations on the bladder bear upon gastric duodenal and intestinal dystrophies in the two following remarkable ways

(1) Hæmatemesis and melæna may be caused simply by petechiasis in the mucous membrane of these parts due to septic foci elsewhere in the body

(2) Petechiasis may end in actual ulceration in the stomach, duodenum, and intestine Consequently it is of the utmost importance in any of the above events to seek and cure a septic focus before excising or operating upon viscera in cases of hæmatemesis, melæna, or hæmaturia Further, it is possible that metrorrhagia or menorrhagia may again be examples of petechiasis due to a septic focus elsewhere in the body

THE ALLERGEN-PROOF CHAMBER IN THE TREATMENT OF BRONCHIAL ASTHMA AND OTHER RESPIRATORY DISEASES

By W STORM VAN LEEUWEN,
W EINTHOVEN, JUN, AND W KREMER

(From the Pharmaco-Therapeutic Institute of the University of Leiden, Holland)

IT is generally acknowledged that almost all cases of bronchial asthma and urticaria belong to the so-called allergic group of diseases, that is to say, the attacks are caused by inhalation or ingestion of substances called allergens—e g, horse-dandruff and other so-called animal proteins, various pollens, and particular kinds of food If the causal agent of the attacks is known, specific therapy may be applied by injection of small quantities of solutions of the allergen In many cases, however, it is impossible to implicate one particular allergen as the causal agent, and non-specific treatment has therefore to be tried

In an article published in THE LANCET in 1921 [1] it was suggested that in allergic diseases the use of tuberculin was the most valuable form of non-specific treatment We have now treated over 500 cases by this method, and our results are as follows · cured, 50 per cent, improved, 30 per cent; failures, 20 per cent These results are valuable, but not satisfactory, it is noteworthy that nearly all investigators who publish statistics on the treatment of allergic diseases estimate their failures at about 20 per cent

Work done during 1923 and 1924 [2] showed us that our failure to achieve more than 50 per cent of complete cures was almost entirely due to the fact that factors of climate played such an important part in these cases We realised that if it were possible to bring all these patients to a high mountain climate and keep them there permanently the problem of treatment would be practically solved Other investigations showed us that the influence of a high mountain climate on allergics is almost entirely due to the relative absence of allergens in the atmosphere The allergens occurring in the air of lower countries we called *climatic allergens*

Since it is impossible to send all asthmatics to high altitudes and keep them there we considered the possibility of making such arrangements in patients' homes that they should be free there from contact with climatic allergens This problem has been studied during the last two years, and we can now state that it has been practically solved Allergen-proof rooms are now used by a number of patients in our country The system worked out by us is so simple and gives such good results that it will probably open up new ways of treating allergic and other diseases Of course this does not mean that the older methods of anti-allergic treatment—including the use of tuberculin—have become useless, on the contrary, they are still of great importance as additional measures But in pure cases of climatic allergy the allergen-proof chamber has become the principal means of treatment

Two Groups of Climatic Allergens

Before describing the new therapeutic method we must first refer to a point which formerly puzzled us considerably, but proved to be a useful starting-point for further work Every physician knows that many asthmatics are better in some places and worse in others, and also that many patients are free from attacks of asthma as soon as they are taken into hospital, even if the hospital is in the very town in which they live The improvement which takes place at the hospital is not due to food, rest, or drugs, for

[2] W S van Leeuwen, Proc Roy Soc of Med (Sect Therap and Pharm), 1924, xvii 19

allergens Furthermore, our observations proved that conditions similar to those in high mountain air may be produced by artificial means in Holland or any other country In this connexion it is noteworthy that our clinic is situated on clay soil in a moist region, which is naturally considered bad for asthmatics

Of course those patients who improved during residence in the clinic were not cured of their asthma As a matter of fact, most of them had attacks again as soon as they went home In this respect, too, the effect of the allergen-proof chamber is similar to the effect of high mountain air This being so, it may be asked why we took these patients into the clinic at all It was done, first, to make a correct diagnosis and to observe whether the case was a "pure" case of climatic asthma, secondly, to determine whether other sensitisations—to products of animal skin or foodstuffs—were present, and, thirdly, to start anti-allergic treatment with small doses of extract of climatic allergens and to determine the efficient dose for treatment Apart from this, admission to the clinic is of great value, since we can advise those patients who belong to the 75 per cent of purely climatic cases to build an allergen-proof chamber in their own homes, or, if this is financially impossible, we may at least instruct them how to change conditions at home by looking after furniture, mattresses, blankets, and the like

Allergen-proof chambers have been installed by a Dutch and a German firm in 45 private houses and have in almost all cases given complete satisfaction The application of the system to private houses is possible as there are two favourable circumstances which have to be mentioned First, it has turned out that climatic allergens of Type A—i e, allergens occurring in the outside air—are of much less importance than those which occur and are formed in the houses, and consequently the simple type of allergen-free chamber is for the most part sufficient, very few patients needing the much more complicated and expensive type which arranges for purification of outside air Secondly, it has proved that even patients highly sensitive to climatic allergens can stand a certain amount of allergen, so that it is not necessary for them to stay in their allergen-proof chamber day and night, and it suffices if they sleep in their chamber and stay in it some hours daily In the daytime they may go out and attend to their work Of course, there are some exceptions in which the cause of asthma is to be found precisely in the place where the work is done, but by this method we have been able to treat successfully cases which have absolutely resisted all other forms of treatment It goes without saying that for safety's sake we give anti-allergic treatment also to those patients who have a chamber at home and try to desensitise them gradually with injections of small amounts of climatic allergens

Whooping-cough and Tuberculosis

Recently we have applied the principle of treatment in allergen-proof chamber to two other illnesses—whooping-cough and tuberculosis Only five cases of whooping-cough have been treated, but the results were so striking as to justify publication, the more so as probably we will not be able to extend our observations in this direction in the near future All our whooping-cough cases came into the clinic during or before the height of the illness, they had violent attacks at least every two hours These violent attacks ceased from the moment they entered the allergen-proof chamber (ventilated with purified air) We did not notice any severe attack with cyanosis, although some attacks, eight at most of a very mild degree of severity, occurred during the first few days After four to seven days the children were free from cough We do not know the explanation of this sudden improvement, but simply report the facts as they may be of theoretical and practical interest

Sixteen patients with tuberculosis of the lungs were admitted to the clinic and kept in allergen-proof chambers They were pure cases of severe tuberculosis with symptoms and clinical signs of the disease confirmed by radiographic examinations In the seven who had sputum examination showed numerous tubercle bacilli Three patients remained uninfluenced by residence in the allergen-proof chamber, but all the others improved In two very severe cases the improvement was only temporary, they could not be saved and died after half a year and a year Improvement was shown very soon after admission to the clinic and consisted of more ease in breathing, much less coughing, improvement in appetite, increase in weight (3 to 15 kg), lowering of bodily temperature, and in some cases reduction in the amount of sputum In three cases with distinct cavities the reduction in the amount of sputum was very marked The ultimate results of the treatment of pulmonary tuberculosis in allergen-proof chambers cannot yet be judged We only want to emphasise that the first result of admission to allergen-free air in 13 out of 16 cases of severe tuberculosis of the lungs was a distinct improvement, so that the conclusion is permissible that also in this respect the advantage of high mountain air may be obtained in low countries by artificial means The lack of ultra-violet rays in our allergen-proof chambers may, of course, easily be made good by the use of quartz lamps

Clinical and Laboratory Notes.

FOUR CASES OF TETANUS FOLLOWING INTRAMUSCULAR INJECTION OF QUININE.

By John Macqueen, M B, Ch B Edin,
SENIOR MEDICAL OFFICER, DEPT OF HEALTH, PALESTINE

In September and December, 1925, four persons died in Haifa from tetanus following intramuscular injection of a solution of quinine bihydrochloride into the buttocks They were all adult males The following are notes of the cases —

Case 1—The patient received injections of 1 g quinine bihydrochloride on Sept 15th and 16th On the same day five other patients had injections of the same solution, two of them were alive and well in January, 1926, and the other three had gone to Transjordania and could not be traced After the injections the patient received dental treatment and suffered from bleeding piles Symptoms of tetanus set in about Sept 27th, 11–12 days after the last injection, and the patient died on Sept 30th No wound was discovered

Case 2—Injections of 1 g were given on Nov 3rd, 4th, and 5th Symptoms began about 28 days later, and the patient died after an illness of 2–3 days on Dec 5th He died out of hospital, but so far as is known there was no wound except that of the injection

Case 3—The symptoms came on 28 days after the last of three injections on Nov 4th, 5th, and 6th The illness lasted 24 hours and the patient died in hospital There was a history of an ingrowing toe-nail which he used to pare No wound was discovered Between Nov 3rd and 6th two other patients received injections (also of 1 g), with the same series of needles (reboiled) and with the same quinine solution, possibly from a different bottle Both were alive and well in January, 1926

Case 4—The fourth patient received his injections on Nov 11th, 12th, and 13th Definite symptoms of tetanus were first noted on Dec 4th, 21 days after quinine was last given, and the patient died in hospital on Dec 7th No wound other than that of the injection could be discovered Between Nov 6th and 13th nine other patients were given injections from the same solution All were alive and well, so far as we knew, in January, 1926, most of them were seen

The quinine solution for the injections in September (Case 1) was prepared before Sept 5th That used during November was made up during October

Method of Preparation—Vaccine bottles (25 c cm) are well washed and rinsed with alcohol The quantity of quinine bihydrochloride required is measured out and placed in a glass measure and distilled water is added to make a 50 per cent solution The solution is filtered and poured into several vaccine bottles These are rubber-capped and sterilised in an autoclave at 15 lb and 120° C for half an hour They are stored in a poison cupboard and a new lot is prepared about every six weeks.

it occurs if the patient is out of bed all day, goes home, and does his work—provided only that he *sleeps* at the hospital.

We have come to the conclusion that two kinds of climate-allergens must be distinguished Probably it will be shown in a few years that allergens of these two groups are of a common nature, but for the present we draw a line between two groups, which we call A and B Group A contains allergens which occur in the outside air, for example, the presence of such allergens in Bristol may induce attacks in a man who is free from asthma in London The nature of allergens of Group A is unknown, although we have been able to prove their existence beyond any doubt Group B contains allergens which occur and are formed in private houses They are absent, or almost absent, in well-organised hospitals Various workers have found examples of such allergens—e g, house dust, grain contaminated with small insects (mites), unknown substances in certain feathers used in pillows, bedding infected—as often happens in private houses, but seldom in hospitals—with fungi, especially *Aspergillus fumigatus*

Most patients are very sensitive to allergens of *Group B, and they are practically* free from attacks if protected from them Protection may be obtained by building in their bedroom a small airtight chamber (Type I) described below A small number of patients are also sensitive to allergens of Group A to such an extent that the chamber of Type I., which only excludes allergens of Group B, is not sufficient; they must be put into a chamber of Type II.

Description of the Chambers

By Prof VAN LEEUWEN and Mr EINTHOVEN.

TYPE I. is an airtight chamber, built of iron or any other material on which bacteria or moulds cannot grow The room must be small—6 × 6 × 9 ft suffices In the front wall of the chamber is a door which shuts tightly, in one of the side walls is a large window, to face the window of the room in which the chamber is to be placed The walls are painted and varnished, so that they may be easily cleaned

The chamber contains an iron bed and an iron chair Mattresses, pillows, and other bedding are ordered fresh from the shop, they are sterilised before entering the chamber and again every two months Before going to bed the patient undresses in his bedroom and then enters the chamber and shuts the door at once; he stays in the chamber during the whole night and he does not take into it any clothes, extra pillows, books, or food The chamber is ventilated by an exhauster which blows in 70 cubic feet of air per minute In one of the side walls is a hole to let the air escape, this hole is connected with an outlet For most purposes it is sufficient if the exhauster draws in air by an iron tube protruding about 30 feet above the roof of the house, in winter, of course, the air must be heated before it enters, and this is easily done by putting some heating system in one of the tubes If zinc tubes are used they must be varnished to avoid the possibility of dust of zinc oxide entering the chamber

TYPE II —The construction of this chamber is the same as of Type I The only difference lies in the methods of purifying the outside air before it enters the chamber Those suggested are as follows —

A *Refrigerator System* —Early in our endeavours to obtain air free from allergens we tried to get rid of the " dust " in the air by means of moisture, and we devised several schemes for the purpose We later found that they were all based on a wrong principle One of the few things we know of the nature of allergens is that they are present in colloidal form and are very easily soluble in water, so that moistening the air or filtering it through moist tissue will never be satisfactory In moist air these water-soluble colloidal particles will always be surrounded by some molecules of water The proper method of getting rid of allergens is to make the air dry by cooling, the water of condensation will then contain a great part of the colloidal material which was previously present in the air Thus the air can be effectively purified by being passed over the cooled surface of a refrigerator before entering the chamber In the clinic for allergic diseases at Leiden there is a refrigerator with a capacity of 4000 calories per hour and a cooling surface of 180 sq. ft This will reduce the dew-point of the outside air by 20° F if about 150 cubic feet of air pass per minute, which suffices to ventilate two chambers of Type II for two patients each The cooled air has to be heated by means of a small central heating system For the most part we obtain a relative humidity of 20 per cent in our chambers, with a room temperature of 65°–70° F, which may be considered sufficient

B *Filters* —One of our first projects was to purify the outside air by means of a filter Cotton filters, which we used at the beginning, proved useless Aided by the kindness of Prof Gray, of Leeds, we tried various other materials, and at last found common asbestos paper to be the most satisfactory We have constructed asbestos filters which have a capacity of 180 cubic feet per minute at a pressure of 25 cm water This pressure may be produced by an *ordinary exhauster driven by an electric motor* Since this filter keeps back tobacco smoke entirely it may be surmised that all colloidal particles of a diameter above 10 μμ are taken away from the outside air It has not been possible so far, however, to put this system on a sound financial basis If a filter has only to free the air from pollen it is unnecessary to use asbestos paper, simpler filters of specially prepared paper being sufficient. They offer very little resistance and in practice they are found useful

C *Electrical Process* —During discussion of the problem of dust-free rooms Prof F G Donnan about three years ago suggested to one of us that we should use the Cottrell process This is based on the following principles —

In the centre of an iron tube (which is connected with the earth) a thin metal thread is placed This thread is connected with a high voltage transformer and rectifier, so that the thread can be charged with about 50,000 volts If air loaded with dust passes through the tube all the dust is thrown to the side of the tube, the air leaves the tube purified

This method has, for clinical purposes, the great drawback that the air leaving the tube contains so much ozone that it cannot be breathed We had to find a device for getting rid of the ozone Dr Nijk succeeded therein by the use of mixtures of various metallic oxides, but this system also, it was found, could not be put on a reasonable economic foundation

Clinical Results.

By Prof VAN LEEUWEN and Dr W. KREMER

More than two years ago a special clinic for the treatment of allergic diseases, based on the principles laid down in the preceding section, was arranged in Leiden For this purpose two private houses were rented, they were damp and rather badly built, and were situated on clay soil in a very moist part of the city In eight rooms of these houses small allergen-free chambers were built and arrangements were made to enable us to ventilate each chamber with outside air or purified outside air

So far about 500 asthmatics have been admitted Of these, about 75 per cent became free from asthmatic symptoms within two or three days, about 15 per cent were distinctly improved after two or three weeks, and 10 per cent remain uninfluenced Some years ago K Turban and L Spengler, in an account of the influence of high mountain air on asthma, stated that at Davos 68 per cent of asthmatics became free from symptoms within two or three days, 25 per cent. were much relieved after two or three weeks, and 7 per cent remained unchanged It is clear, then, that our results are the same as those of the Swiss authors, which affords undeniable evidence for the correctness of our view that the beneficial influence of high altitude on asthma is due to the lack of climatic

Medical Societies.

MEDICAL SOCIETY OF LONDON.

A GENERAL meeting and conversazione of this Society was held on June 13th, Sir HUMPHRY ROLLESTON, the President, in the chair Following the business meeting, the annual oration was delivered by Prof HARVEY CUSHING (Harvard University, U S A)

The PRESIDENT, in a few introductory words, referred to the importance of Prof Cushing's contributions to medical literature, and especially to his work on the surgery of the central nervous system He was outstandingly fitted to the happy definition of the surgeon as a " physician who can use his hands," and he could use his pen with equal facility Everyone must have been charmed by his Life of Sir William Osler, his teacher and friend

Prof HARVEY CUSHING took as the title of his oration

THE SURGICAL ASPECTS OF ACROMEGALY

He said that though the medical man began his professional life with a general training he soon found that there were certain maladies or phenomena of disease which particularly interested him, and which, through force or opportunity or circumstance, engaged his attention It was by progression from the general to the particular that specialisation arose, and though in the process the field might narrow, the point of view might broaden

Those who could go back to the 'nineties would know that the pituitary body was then too inconspicuous an object to attract much attention , if noticed at all it was brushed aside as a vestigial relic of no recognisable importance There were, however, glimmerings of its relationship to the disorder to which Pierre Marie had recently given a baptismal name Once pointed out, this disorder was easily recognised, though for a time it was regarded as a freak of nature which eclipsed understanding, nothing then being known of the function of the pituitary body or of its relation to other glands having an internal secretion How different the aspect now, when the problems of endocrinology were absorbing the attention of a host of investigators, who, almost monthly, were adding to knowledge on the subject

There were certain general principles on which the profession had come to base its conception of the way in which the disorders of the ductless gland affected the body The first of these arose from the presumption that there were counterposed states of primary under-function and of primary over-function for every single member of the so-called endocrine series And it was assumed that these two states, in the case of every gland, would evoke their own peculiar clinical syndromes Some of these, which were already recognised, and some—particularly the deprivation states like myxœdema, diabetes mellitus, eunochoidism, and tetany—could be experimentally produced in animals , the states of glandular over-activity had for the most part proved difficult to reproduce experimentally

Surgery had played no small part in the elaboration of this theory Enlargement of the thyroid was for all to see, and in localities where goitre was endemic the surgeon had primarily been induced to operate upon cases in which life was endangered or made insufferable owing to pressure by the enlarged gland on the trachea These procedures had proved hazardous It had then become evident that a residuum of thyroid tissue must be left, and that the parathyroid glands must be spared if subsequent health, and even life, was to be maintained The pituitary problem however, was far more difficult, and not until skiagraphy was sufficiently perfected to be reliable, had it been possible to tell with any certainty whether that gland was tumefied Its inaccessibility had long kept it out of the way of surgical temptation, and even its experimental removal in animals was difficult and gave contradictory results, largely on account of coincident adjacent lesions of the nerve centres, which possibly presided over the activity of the neurohypophysis

Function of the Pituitary Body

One of the first questions to be raised in regard to acromegaly concerned its likely connexion with pituitary tumours And at last investigators were coming to close quarters with the riddle The physiologists and biochemists had chiefly given attention to the active substance discovered in extracts of the neurohypophysis, the pathologists had had some success in differentiating certain of the hyperplasias and other tumefactions affecting the gland , the morphologists had shown how, in the development of Rathke's pouch, the epithelial *anlage* of certain of the congenital tumours might arise, whilst the experimentalists had laboriously undertaken to determine the secondary effects of removing part or all of the gland.

Early experiments showed that the hypophysis secreted a substance or substances which not only influenced growth, but also had a marked effect upon the activity of the reproductive organs Physiologists had discovered an active principle only in extracts of the posterior lobe of the gland, this principle being a stimulant to growth Menstrual disturbances were common in women who had disease of the pituitary, whatever the nature of that disease might be Prof. H M Evans had shown that fresh extracts of the anterior lobe would not only interrupt œstrus in an adult female rat, but would prevent its onset when it was given to pre-adolescent animals The same worker had found that when intraperitoneal injections of these extracts were continued over a long time the growth of the animals concerned was greatly accelerated, and that gigantism could in this way be experimentally produced T J Putnam had succeeded in doing this, and it had been shown that the pars anterior actually contained a growth-stimulating hormone This important fact would doubtless stimulate the biochemist to search for the chemical principle When this had been finally isolated, the treatment of clinical states of anterior pituitary lobe deficiency would be revolutionised These experiments had not produced acromegaly, but only gigantism, though both these conditions could be ascribed to excessive secretion of the anterior lobe. Prof P E Smith, of Leland Stanford University, had devised an operative procedure whereby hypophyseal or parahypophyseal lesions could be accurately made, with results which were far more dependable than any previously attained, and the possibilities of replacement therapy to atone for this glandular deprivation had been for the first time demonstrated

Prof Cushing had something to say in criticism of some of the terms in current use in relation to hypophyseal disease Did cachexia hypophyseopriva, due to destruction of the gland, really exist? He suggested that such a term as macrosomia might replace acromegaly , it would permit of its reverse condition being spoken of as microsomia

Effects of disordered pituitary function on organs other than the sexual ones had also been investigated. In autopsies on four cases of acromegaly, not only was there splanchomegaly but also hyperplasia of the thyroid and parathyroid Owing to a careful study of the rat and its habits, an immense field had been opened up in relation to pituitary function It was clear that this structure conducted an orchestra, and derived from it harmony or dysharmony overtones or undertones, according to its physiological mood.

Hypopituitarism

Clinical states occurred which suggested that the patient suffered a complete deprivation of pituitary substance It was now occasionally possible to remove the pituitary gland apparently in its entirety, even in the adult It had long been noted in the case of animals that young ones stood the procedure much better than did adults If it was clear in a

Before use the rubber cap is dipped in iodine The needle pierces the cap

Technique of Injection —Injection is made into the gluteal muscles on the outer part of the buttocks The skin is prepared with 3 per cent tincture of iodine Two or three needles are boiled and reboiled between each injection Boiling of syringe and needles is for 15 minutes in the first instance After injection hot fomentations are used

There are certain points of interest in connexion with these cases The incubation periods were long in two cases 27 to 28 days, in one 21, and in one 11–12 The illnesses, on the other hand, were unusually severe The time between onset of symptoms and death was in no case more than 72 hours

The conclusion was reached that the infecting spores were in all four cases introduced at injection There did not appear to have been any obvious defect in the manner of preparation of the skin, the technique of injection, the sterilisation of syringe and needles, or the preparation and sterilisation of the solution Similar methods had been employed for a considerable time and were used in military hospitals during the war The cases remind us that quinine solution causes necrosis of muscle-tissue and that necrosed tissue shut off in this way from the air may form an ideal nursery for tetanus spores if they happen to gain entrance It is not easy to maintain a technique which will exclude all possibility of introducing them They provide a further argument in favour of the oral as compared with the intramuscular route for the administration of quinine whenever possible

The subject is dealt with by Sir D Semple in Memoir No 43 (New Series) of the Series of Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India, published at the Government Printing Press, Calcutta, in 1911, and entitled "The Relation of Tetanus to the Hypodermic or Intramuscular Injection of Quinine"

A CASE OF
AURICULAR FIBRILLATION
OF FIFTEEN YEARS' DURATION

BY E E LASLETT, B SC LOND, M D MANCH

THE following case seems worthy of record

Mrs K first came under my care in July, 1910 She was then 48 and had five children She had had rheumatic fever 20 years before, but had enjoyed fairly good health since She complained of breathlessness and swelling of the feet The apex beat could not be defined There was a systolic murmur at the mitral area, and the rhythm was irregular owing to the presence of frequent auricular extrasystoles

In January, 1911, she became much worse The dropsy increased orthopnœa was present, and the pulse became very rapid and wholly irregular It was found that the venous pulse was now of the ventricular type (auricular fibrillation) The heart slowed in a few days under ♏ xlv tinct digitalis daily and there was general improvement in her condition A faint diastolic murmur could now be heard at the left side of the lower end of the sternum The improvement continued till April, when the more serious symptoms returned There was again a rapid response to treatment and the pulse fell to 40 with a tendency to coupled beats The dose of digitalis was now halved and kept at this amount for some time

During the next ten years she was able to do her own housework for the most part, although in the latter part of this period attacks of bronchitis became more frequent and prolonged She was kept almost continuously under the influence of digitalis Œdema of the feet was often present to a slight degree, but it disappeared during her periodic rests in bed In the winter of 1920–21 she was very ill with increased dropsy, cyanosis, and enlargement of the liver In the following winter she was in bed for several months, and from that time till her death she was kept almost entirely in her bedroom As a result of the increased rest, and, probably also owing to the development of partial block, the heart tended to a slower rate, so that it was found possible to reduce the amount of digitalis to ♏ xxiv and even ♏ xv daily

In April, 1922, she had an attack of aphasia, possibly embolic in origin This passed off in a few days, and her mental condition became apparently normal On the whole she had little physical distress Though she chafed at her enforced rest she was able to amuse herself with reading and light feminine occupations, and she was probably in greater comfort than she had been for a number of years At the end of 1926 she was sitting up in bed apparently as well as usual when she suddenly fell back unconscious and died in a few hours

Dr John Cowan, in his Gibson lectures,[1] relates a case in which fibrillation was known to exist for nearly 12 years Four years after the onset of fibrillation the patient had her sixth child She died at the age of 39 In the case here recorded fibrillation was present for 15 years, and this in spite of the fact that at the time of its onset the patient was nearly 50 years of age and showed signs of a failing heart One is tempted to suggest that this change of rhythm, although it is so often an added embarrassment to a damaged heart, may have been helpful rather than injurious to this patient, because her heart responded so readily to digitalis and she was fortunately able to continue treatment during the whole of her illness

Hull

A NOTE ON
EPILATION BY THALLIUM ACETATE *

BY F R CURTIS, M SC, M B, CH B LEEDS,
KING'S COLLEGE, STRAND

As the result of experiments begun by A Buschke in 1900 and carried on by himself and others,[2] it has gradually been established that thallium acetate, which 30 years ago had been given up as dangerous by Sabouraud, can safely be used for epilation in cases of ringworm in young children as an alternative to X ray epilation which, as is well known, possesses disadvantages in these cases Early this year G B Dowling and R Kelman,[3] and M Drummond,[4] reported the results of using this method for epilation in children suffering from ringworm Both these reports suggested that the preparation of thallium should be fresh, because the drug might deteriorate As this supposed deterioration is a matter of considerable importance it was thought advisable to investigate it

Using rats as experimental animals I find that epilation occurs constantly on the seventh or eighth day after the subcutaneous injection of a solution of thallium acetate equivalent to 7 5 mg per kilogramme of body-weight In all cases the solution was freshly made immediately prior to injection The best site for demonstrating epilation at that period after injection is, as Dixon[5] points out, at the back of the head and neck and just behind the ears

Solutions of thallium acetate, prepared and placed in sterilised ampoules three months previously, were tested on a series of rats using the dose given above. Epilation occurred promptly on the eighth day after injection, thus showing that the date of the preparation is not of any moment

Another point that may be worthy of mention is the danger of giving a second dose too soon after the first dose Rats may be given a dose of 22 5 mg per kg of body-weight subcutaneously and remain perfectly healthy in every way, though, of course, epilation occurs freely But if 7 5 mg per kg is given and then three weeks later a further 15 mg per kg is given (making the same total of 22 5 mg per kg) the rats die within a few days, having shown loss of appetite and weight, conjunctivitis, stomatitis, and epistaxis This cumulative effect of thallium is very marked and Buschke advises not giving a second dose within two to three months of the first

Experiments on the mode of operation of thallium are now being carried out at King's College and, it is hoped, may throw some light on the problem acromegaly, apparently with success When a proper and reliable system of substitution-therapy had been established probably the operative risk would be less

---

[5] Dixon, W H Proc Roy Soc Med, June, 1927

He had made an effort, in this address, he said, to evolve some order out of chaos, and even if he had done no more than indicate the true latitude and longitude he would feel content

Sir Charles Ballance proposed a cordial vote of thanks to Prof Cushing for his address, recalling the time when, in 1892, he had met the orator, who had come to Queen-square National Hospital as a student He said Prof Cushing had energy and a scholarly mind, and he expressed his intense admiration for him as a man and as a worker in neurology, of which he was a master

Sir StClair Thomson seconded the vote, and after it had been supported by the President it was carried enthusiastically by Fellows rising in their places

---

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF LARYNGOLOGY AND OTOLOGY

The annual summer meeting of these Sections was held from June 9th–11th, the Presidents, Dr Andrew Wylie (Laryngology) and Dr Dan McKenzie (Otology) in the chair On Thursday the Laryngological Section met and Mr F B Gilhespy read a paper on

Chronic Hyperplasia of the Upper Jaw

One of his purposes, he said was to draw attention to the efforts made to include cases of this disease under the wider heading of osteitis fibrosa ; another was to indicate some similarities between the condition and that known as otosclerosis In the eight cases recorded by Westmacott the patients suffered from a bony unilateral enlargement of the upper jaw, and six of them had septic teeth in the affected portion At the operation the new bone could be gouged away, as it was somewhat soft The interstices of the bone were occupied by a thick layer of actively proliferating osteoblasts, among them being a few osteoclasts The vascular supply was rich, and there was an abundance of connective tissue cells Westmacott's view was that in these cases there was a reversion of the bone to the embryonic type In none of the eight cases was the premaxilla affected, and this supported the idea that the condition started in the alveolus In cases of this chronic hyperplasia the cranial bones might be remarkably thickened, so that the inner and outer tables could not be differentiated, the structure of the bone being homogeneous Mr G J Jenkins had shown that an osteoporotic process might affect the region of the oval window in osteitis deformans, which some regarded as a form of osteitis fibrosa Mr Gilhespy asked whether chronic hyperplasia ought to be regarded as a simple fibrous osteitis, or whether it was a localised dystrophy of bone, depending perhaps on a biological variation and incited to activity by various causes, of which infection from the mouth or teeth might be one

Mr Walter Howarth referred to two cases of his own, in one of them he had operated seven years ago, and the condition had remained stationary ever since The disease had started in the alveolus, and he considered that dental sepsis was the primary cause —Dr W H Kelson had had two instances of this hyperplasia, neither bearing any relation to oral or dental sepsis Severe and extensive removal had been found to be unwarrantable —Mr Ritchie Rodger spoke of a case of what was regarded as leontiasis ossium, with large bosses on the left superior maxilla and one on the mandible The patient disappeared for four years and then came having several bony rhinoliths The Wassermann reaction, which previously was negative, had become positive He suggested this test being done in all such cases as a routine —Mr T. B Layton thought there was much evidence of an infective cause of this condition —Mr Douglas Guthrie showed two slides of specimens of the condition in cases in which there was no dental sepsis —Mr James Harper spoke of three cases under his care In one a microscopical examination had been made, showing fibrous changes in the bone, but no evidence of malignancy In one case it would be necessary to remove the jaw in order to save the patient's sight —Dr J S Fraser said these cases supported his view that otosclerosis was a chronic inflammatory process —Dr Logan Turner recommended the appointment of a committee to investigate the subject

Mr Howarth read a paper on the

Technique of Laryngofissure

He contended that there were several reasons why tracheotomy should not be done as a preliminary to this operation, for instance, surgical shock was added to by it and blood and secretions were permitted to enter the lungs Also, direct stimulation of the mucosa did not make for smooth anæsthesia and might facilitate the implantation of cancer cells He used intratracheal ether for the operation, and did not perform a preliminary tracheotomy In all these cases the surgeon should be close at hand for 24 hours after the operation He no longer removed the thyroid ala though at one time it was his custom. Diathermy was a great help in stopping persistent oozing, but of course, it could not be used with ether Diathermy merited careful consideration not only for oozing, but as a means of actually removing the cord

The President (Dr Wylie) said that in two cases in which he did the operation without first performing tracheotomy he had great difficulty on account of hæmorrhage, and tracheotomy had to be done immediately afterwards because the patient coughed so much and he became afraid of pneumonia Some patients had bronchitis for a time when ether had been used —Prof Georges Portmann (Bordeaux) said that at his clinic at Bordeaux the practice was to do the operation without preliminary tracheotomy, and under local anæsthesia If, shortly after operation, the patient had respiratory troubles it was easy to do tracheotomy then —Dr Sugara (Buenos Aires) said that in these cases electrolysis could be used He did not do tracheotomy first Great care was taken to stop bleeding at the end of the operation, and electrolysis, very slowly applied, was useful —Mr N S Carruthers contended that some leakage of blood generally took place, and that this might account for the cases in which there was severe bronchitis —Sir StClair Thomson said that Sir Henry Butlin and Sir Felix Semon did not remove the ala of the thyroid, and he himself had at first followed their lead But he had two or three cases in which some necrosis of cartilage occurred. and portions were coughed up during convalescence Since he made a practice of removing the ala he had not had any cases of necrosis On the principle of "safety first," he did preliminary tracheotomy first, especially as it was not dangerous and did not cause shock The only reliable data were those based upon results in large consecutive series of cases He had had only three operative deaths—i e , deaths occurring within a few months of the operation—in his series of 80 cases —Mr W M Mollison spoke favourably of his use of intratracheal ether in two or three cases of laryngofissure The anæsthetic could be washed out of the patient by the insufflation of air or oxygen at the end of the operation

Mr Howarth, in reply, said he had had three deaths following laryngofissure—in earlier operation days—chiefly owing to blood entering the trachea. He did not think any leakage could occur during the administration of the anæsthetic

Mr Layton read a paper on the

Relation of Nasal Polypi to Inflammation of Accessory Sinuses of the Nose

He said his reason for ventilating this question was that for some time he had been disappointed given case that there was a tumour of the hypophysis, was the surgeon justified in removing the gland in its entirety? Or was it possible by such a procedure to inflict on the patient symptoms which might be worse than those it was sought to relieve—i.e., tumour symptoms? Cases had been seen in which the patient was suddenly seized with severe headache, became stuporose and comatose, with a markedly subnormal temperature, and died in the coma. Such a syndrome would be very puzzling to the pathologist unless he realised, and was alert to the possibility, that acute lesions in the pituitary body might provoke such a clinical picture.

Hypopituitarism was the reverse condition to acromegaly. The effects were different according to the period of life—whether the state occurred in pre-adolescence or in adult life. He showed a photograph of a young women, aged 28, a dwarf. At 8 years of age she had a very severe infection—its nature was not clear—and was unconscious for a long time. After recovering from that acute condition she scarcely grew at all for 10 years. At 28 years she was just over 4 feet in height and weighed only 75 lb. It was a case of primary deficiency of the anterior lobe of the pituitary lobe alone. She was sexually infantile, and had never acquired any secondary sexual characters, while the other ductless glands were atrophied.

Photographs were also shown of a case of early senility, the subject being a young woman. The open epiphyses of the fingers, shown by X rays, indicated that by appropriate substitution-therapy she could be given the usual adult womanly characters. These people with pituitary deficiency died of old age in their 'teens, and to relieve their condition recourse must be had to substitution-therapy. This was much more hopeful in these individuals than in cretins, for however much the cretin might be made to grow as a result of appropriate medication, he always remained a dull and mentally incapacitated person. The pituitary cases might even, as a result of treatment, become precocious.

CONDITIONS ASSOCIATED WITH TUMOUR.

Up to the present point, said Prof. Cushing, he had been speaking of non-tumour states. When the pituitary condition was associated with tumour there were many names applied to it. The case on which was based the term Frohlich's syndrome was that of a boy, with a tumour of the gland, who was adipose and sexually indisposed. Almost always the cases which began with a tumour in childhood were those in which the swelling originated from a relic of Rathke's pouch. There might not be any actual enlargement of the sella, but compression was exerted on some portion of the gland. There might exist a combination of symptoms of insufficiency, and these symptoms would usually be much less clear than in the cases of pure anterior lobe deficiency due to the presence of infarcts. When the disease began in early life, its subjects were dwarfed, as the anterior lobe was compressed. When the disease did not show itself until adult life, stature was retained.

Prof. Cushing showed slides to illustrate the frontal approach to the sella with exposure of the chiasma. He was careful not to belittle the seriousness of the operation, especially as these tumours were very adherent, and there was the risk that the surgeon might destroy the hypophysis or its important blood-supply, thereby provoking serious secondary symptoms. In about 83 per cent. of the cases enlargement of the sella could be seen by careful skiagraphy. Patients might be either adipose or lean, according to the part of the gland affected.

He also dealt with hypopituitary cases associated with adenoma. This was a very important class of case, as pituitary disease which led to gigantism was invariably associated with adenoma. What ought the surgeon to do in cases with adenoma? In his own clinic there had now been two or three hundred of these cases which had been operated upon—adenomata of all types. He showed the photograph of a typical case. The man was blind in one eye, the other was afflicted with optic atrophy, he was adipose, and had sexual dystrophy. His adenoma was attacked sufficiently radically to relieve the pressure on the chiasma and to prevent vision from being lost altogether. But was that enough? Was the surgeon justified in going ahead and attempting more thereby running the risk of setting up deficiency states?

The cases with adenoma he divided into the primary, the transitional, and those having an affinity for an acid diet. Some of the tumours in acromegaly were of enormous size. He showed a photograph of the site of a large tumour in the brain of a giant of 8 feet, in whom adenoma was not suspected, as he had no visual disturbance and did not complain of any intracranial symptoms. His sella turcica was seen by X rays to be small, yet he had this extensive intracranial adenoma. In the States the practice was growing to operate on these people before their acromegaly became very pronounced or serious secondaries were manifest. In the case of the first man on whom he operated for the condition, in 1909, he was struck by the great shrinkage of the tissues of the patient's hands. The tumour in his case was small and the immediate purpose of the operation was to attempt relief of the headaches. That result was achieved and 19 years later he was still living, but the acromegaly had steadily progressed notwithstanding. No doubt the relief of the headaches was brought about by freeing the hypophysis from exterior pressure. In another case, that of a woman, he had operated for the relief of intense headaches, and she was much better for three or four years. Then a radical operation was done by another surgeon (as Prof. Cushing was in Europe) and the gland was removed; now the original acromegaly had been transformed into a condition of relative pituitary insufficiency, a preferable state from the patient's standpoint.

The Criteria of Success.

In conclusion, Prof. Cushing said there did not yet exist a standard or criterion of what the surgeon or physician had accomplished in the kind of cases under discussion; there was nothing comparable to the basal metabolic rate by which the activity of the thyroid could be assessed. Still, progress was now being made in this direction. Most of these patients had a high metabolism. Was that due to the pituitary lesion or to the associated or secondary hyperplasia? The crucial indication was what happened to the patient when his hypophysis was removed. Even a partial operation would diminish the metabolic rate. The latter, and the sugar tolerance, were likely to give the criterion of accomplishment, as in the case of thyroidectomy. These patients were very apt to have a relative hyperglycæmia; could this be dissipated by operation? Those were the lines along which work in the States was proceeding.

It was yet too soon to speak with any finality of the effects of operations in this region. Operations were, in practically all cases, done through the nose. Unless the contents of the sella were completely evacuated it was impossible to be certain that some remnants of adenomatous tissue had not been left behind, and these were at any time liable to revive and produce a repetition of the former symptoms. He contended that the fact that any improvement could be brought about, even though it might be only temporary, should be an encouragement to go on. He had no wish to belittle the complexity of the subject. How far it was safe for the surgeon to go, how near to total evacuation of the causal adenoma he might approach, only experience could show. Serious consequences would follow damage to the hypothalamic centre. Trans-sphenoidal procedures from below were blind operations, with a risk of resultant rhinorrhœa and infection. The 4 per cent. operative risk which was the present figure in his clinic was a good one, he submitted. Where vision was impaired the attempt was made to relieve it and the surgeon carefully felt his way. In several cases having a small sella operation had been done with the object of checking the 51 cases The physical conditions found seemed to indicate that the deafness was not a mere accident.

Mr **Richards** said the deafness complained of had existed for periods of from two to ten years, and its progressive increase was the invariable rule All the patients except one complained of tinnitus but evidence as to its duration was unreliable A history of vertigo was elicited in six cases of paracusis in five, of recurring colds and catarrh in ten, of recurrent huskiness in five and of pain such as earache and headache in nine. A family history of deafness was forthcoming in only one instance. In several cases there were varying degrees of septal deflection but without evidence of infection Marked dental disease was conspicuously absent Mr Richards gave a large number of results of hearing and other tests

Mr G J **Jenkins** considered that the term "chronic middle-ear deafness" was misleading The pathology given in most text-books was obviously only speculative, the syndrome seeming to resemble that of an imperfectly described otosclerosis He had not known middle-ear deafness to be progressive in the sense which was implied by the title of the discussion which could be attributed only to middle-ear changes

The **President** (Dr **McKenzie**) gave a clinical review of some progressive cases of the condition among his private patients In 288 cases there was catarrh in 80 residual cicatrisation in 136 active suppuration, in 206 otosclerosis while in 38 there was a combination of three of these conditions In most of the cases tinnitus was the earliest symptom having preceded the deafness by months or years The condition of the membrana tympani gave no indication of the presence or absence of deafness This type of deafness could not be cured nor even arrested by curing the originating catarrh; yet it could be said that the disease process itself was a self-limiting one, as it did not go on to the entire destruction of function He discussed various possible ætiological factors.

Mr H **Norman Barnett** considered that progressive middle-ear deafness could be divided into (1) that following long antecedent middle-ear suppuration, or secondary to tonsil infection or septal deflection, and (2) that in which these factors were absent but in which there had been infection through the Eustachian tube, or other trouble His treatment was directed to causing absorption of the deposited material and the breaking down of adhesions by oto-massage of the tympanic membrane ionisation over the mastoid, and the passage of various vapours into the middle ear He showed three successful cases —Dr **Fraser** thought that the best classification of these cases was into those with normal tympanic membranes and those with abnormal tympanic membranes In his experience, chronic catarrhal otitis media was now a diminishing quantity, whereas otosclerosis was on the increase —Sir **James Dundas-Grant** believed that many cases of chronic progressive middle-ear trouble were secondary to a narrowing of the walls of the Eustachian tube A negative Rinne might be due to unilateral nerve deafness

Mr **Somerville Hastings** dealt with auditory intelligence, which had much to do with the apparent hearing acuity as tested by the audiometer He believed that otosclerosis properly so-called was very rare He thought the right course was to search carefully for sepsis in every case and treat it A good result might not ensue in every case, but it would occur in a sufficient proportion to make it worth while

Mr J. F **O'Malley** said that in some of these cases there was evidently a hereditary factor—namely, a definite middle-ear catarrhal trouble which led to deafness During a cold there was definite deafness, but on losing the cold the hearing was restored. If hearing did not clear up, an otosclerotic change took place in the labyrinth. He thought otosclerosis was becoming more frequent.

The discussion was continued

Dr **Graham Hodgson** demonstrated a large series of radiograms of the normal and abnormal labyrinth, and Mr **Watkyn Thomas** gave a clinical description of the cases illustrated

Cinematograph Demonstration.

On Saturday morning, before the discussion of clinical cases Prof **Portmann** gave a cinematograph demonstration of an operation for draining the saccus endolymphaticus for the relief of vertigo He began his dissertation by discussing the comparative anatomy of the auditory apparatus of various orders and species leading up to that of man He then passed to a consideration of the physiology and function of the saccus endolymphaticus and minutely described the surgical entry to that structure for the purpose of incising and draining it for the relief of vertigo In two of his five cases there had been a complete disappearance of the vertigo The operation, he declared, was a good one and was not dangerous in the hands of an otologist It was intended for cases in which other forms of treatment had failed to relieve the vertigo

Dr **Jobson Horne** gave an epidiascopic demonstration of morbid specimens of the saccus endolymphaticus showing the course of the disease, and the results which ensued in a number of cases He said this structure might be regarded as an instance of how the vestigial remains of an embryonal structure might become a source of danger.

Sir **Charles Ballance** expressed the thanks of the Section to Prof Portmann for his admirable demonstration and said that perhaps operation in the way indicated might be tried in some cases of deafness as well as for vertigo

A discussion followed

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

At a meeting of this Society held on June 2nd, Dr E **Rivaz Hunt**, the President, in the chair, Dr E R **Fothergill** opened a discussion on

Mental Exhaustion and Drug Addiction

To the sufferer from mental exhaustion, he said, the advice of friends is generally worse than useless, and until the patient settles down to deal with his trouble, and stops thrusting it back into the subconscious all else will fail The first step to be taken is to secure an appropriate atmosphere and the services of an attendant The patient should go to bed, and after constipation—from which these patients usually suffer—has been dealt with, he should be given full diet He should be encouraged to get his brain to sleep until the physical state has been re-established, by which time many of the symptoms will have disappeared It will then be time enough to discover from the patient the cause of his illness and to treat it As much sleep as possible should be obtained At first no books or papers should be allowed, but after a while the patient will probably ask to see a picture paper The date on which this happens should be noted. The relatives should not have any communication with the patient except by an occasional postcard, but the doctor should be assisted by them to discover the possible cause of the illness Records of weight should be taken at intervals of 14 days The patient must first be got to believe that there is no physical or mental disease and that his trouble can be dealt with; he must cease deploring the past and dreading a repetition of it, and must be encouraged to turn his thoughts to the future into a constructive channel. Relatives either regard the question of certification with horror or find it attractive because of ulterior motives Great care must be exercised There are with the traditional treatment of nasal polypi by pulling them away Unless the case were one of a single polypus beneath the middle turbinate he did not find that this method was curative, in other words, for multiple polypi this treatment was no more than palliative He asked whether polypi ever existed unless there was coexistent disease of a sinus When there was no sinus disease the polypi were in large airways, and seemed to be in the nature of a hypertrophy to compensate for the extra size of the airway This type was, he considered, best left alone In most cases of multiple polypi the underlying disease was an inflammation of accessory sinuses Nasal polypi might be associated with catarrhal inflammation in the ethmoid and the maxillary sinus He did not think that acute catarrhal sinusitis ever became acute suppurative sinusitis, his view was that from the beginning they were distinct from each other When a sinus was the seat of acute suppuration he did not open it His treatment was to attempt to remove the whole ethmoid by an external incision, so as to avoid damage in the region of the olfactory nerve and the cribriform plate

Dr W S **SYME** said he believed that in every case of multiple polypi in the nose there was disease in the antrum as well as in the ethmoid cells His rule was to open the ethmoid, and he had never regretted having done so —Mr C A S **RIDOUT** thought that the external operation was not done in enough of the cases of multiple polypi of the nose —Dr J S **FRASER** said he did not feel that he ought to operate on the antral mucosa for nasal polypi, as in a number of such cases which he had investigated he had found it was healthy Proof-puncturing and washing out the antrum gave a good indication as to whether it should be operated on If after clearing the nose the fluid returned at once and freely, obviously the antrum was not filled with polypi If, however, some force was needed to send the fluid through the syringe, there was obviously obstruction, and the radical operation should be performed —Dr **SUGARA** said that the ethmoid was not implicated in all these cases, because treatment directed to it had no effect in some instances Radical operation should be carried out when polypi recurred —Mr J **ADAM** laid stress on the importance of pressure in the causation of polypi An uvula, if caught between two enlarged tonsils, became polypoid Polypi would continue to form until the pressure was relieved —Mr **GILHESPY** thought that the external operation could not be done through a small incision, the procedure needed to be thorough, and he always used a longer incision

Mr **DOUGLAS GUTHRIE** read a paper, in collaboration with Mr N **DOTT**, on the occurrence of

Brain-tissue in the Nose,

the so-called nasal glioma They said that the downward extension of a cerebral tumour towards the nasal cavity seemed to be very rare They quoted a case of glioma of the frontal lobe of the brain, with an extension into the left nasal cavity

The patient, a man, aged 33, was admitted because of sudden coma, and symptoms suggesting cerebral compression There was no history obtainable of any nasal or aural discharge Following a gun explosion, deafness in the left ear occurred suddenly Headache, vomiting, and nausea came on later A week before admission there was sluggish cerebration, and the pulse-rate varied between 54 and 60 The temperature was consistently subnormal The operation performed was the left subtemporal decompression of Harvey Cushing, and evidences of a deep-lying vascular tumour were found An attempt was made to expose this The temperature rose to 105 4° F, and it was very difficult to keep it down The wound healed soundly, but he died, after a relapse, on the thirteenth day The tumour, it was found, had been growing backwards and invaded the motor fibres of the internal capsule There was seen to be a marked convolutional flattening, and a projection at the site of the decompression

Prof **PORTMANN** said it was very difficult to know whether such tumours were simple gliomata or glio-sarcomata —Dr **FRASER** asked whether there was anything distinctive in the appearance of the nose in cases of this kind which could be taken as a warning that something more than ordinary nasal polypus was being dealt with —Mr **GUTHRIE** replied that this patient seemed to have an ordinary polypus, but perhaps the polypus was greyer and harder to the touch than usual

Mr M **VLASTO** contributed a paper on

Meningitis Originating in the Sphenoidal Sinus

The sphenoidal sinus, he said, could be regarded as the carrying site of organisms of a non-thrombosing type, usually of low virulence In the case of meningitis due to infection by other pyogenic organisms, this sinus was a seat of active inflammation Intracranial complications of sphenoidal sinus suppuration fell into one of the three following groups (1) meningitis, (2) thrombophlebitis of the venous sinuses, (3) meningitis and thrombophlebitis Of 42 cases collected by Sir StClair Thomson, 30 died of basal meningitis, and in 17 cases this was the only predominant lesion He described a typical case, which was reported by Roughton, the patient dying 56 days after admission to hospital At the autopsy basal meningitis was present, a thick layer of pus being between the region of the optic chiasma and the pons Mr Vlasto thought there were many reasons why this condition was not recognised before death Patients frequently did not realise the gravity of a purulent nasal discharge, and failed to report it And the diagnosis might be side-tracked by the coexistence of suppurative middle-ear disease After every death from meningitis, the post-mortem examination should include the opening of the sphenoidal sinus cavities When an otitic cause of a case of meningitis had been diagnosed and the operative findings were not conclusive, the possibility of sphenoidal sinus infection should be considered

Dr P **WATSON-WILLIAMS** spoke of the importance of exploring the sinuses in mastoid cases as a routine procedure, even in children —Dr **LOGAN TURNER** urged the need of careful microscopical examination at autopsy, as involvement of the cavernous sinus might be shown —Sir **STCLAIR THOMSON** regretted that examination of the sinuses did not seem to be part of the routine post-mortem examination in all hospitals when the lesion was cranial It could be done without disfiguring the cadaver

Dr **SYME** read a paper in which he gave reports on three bronchoscopic cases, the findings in which prompted him to urge that this form of examination should be done more often

Progressive Middle-ear Deafness

On Friday morning the Otological Section listened to a number of papers on this subject

Dr G **SCOTT WILLIAMSON** and Mr **HORACE RICHARDS** read a joint paper in which they submitted a preliminary analysis of a series of cases of chronic deafness, showing lines of possible investigation into the ætiology Only cases of idiopathic deafness were taken, and all the aspects—cardiac, respiratory, digestive, urinary, neuromuscular, genital, and hæmopoietic—were examined It was not contended that these tests added materially to the information furnished by the ordinary clinical examination Fifty-one cases were examined, and seven of these showed signs of established disease Treatment improved the general condition and with it the tinnitus, which was no longer continuous The 44 other cases were within the normal, but showed a tendency to tachycardia and their cardio-respiratory balance was easily disturbed Many facts pointed to the deafness having been started in school life, when there was a low auditory acuity, a real defect in regard to education In all the 51 cases the nose was small and thin, with a delicate bridge and attenuated skin, the alar muscles were atrophied, and the nostrils no more than slits But the patients were not mouth-breathers, though they all had nervous instability. There were only five males in

Treatment of Diabetes Mellitus

Fourth edition By O LEYTON, M D , F R C P , Physician to the London Hospital London Adlard and Son, Ltd. 1927 Pp 98 6*s*

THE discovery of insulin and the revolution which it has worked in the treatment of diabetes has necessitated a new edition of Dr Leyton's book and caused a change of its name from "The Modern (Allen) Treatment of Diabetes Mellitus" The new edition has been largely rewritten and is now a plain statement of Dr Leyton's views and practice, set out in simple language A glossary of medical terms is included so that patients may read and understand In the preface is a statement of some importance showing clearly the ideals on which the author works He says : "One has reason to believe that the beta cells of the islets of Langerhans regenerate in time, but the process is a slow one, and the recovery may take years to become complete This chance of recovery makes it advisable for all patients except those in extreme old age to arrange a diet which suffices to nourish their bodies and sufficient insulin to keep the blood-sugar below 0 15 per cent , and thereby avoid over-stimulation of the newly formed insulin-producing cell, which would lead to its early destruction" The importance of care in making the diagnosis is emphasised and the condition of renal glycosuria or, as Dr Leyton prefers to call it, negligible glycosuria, is explained very carefully The test for sugar tolerance by giving the dextrose intravenously seems rather complicated and the alternative method of allowing the patient to eat an ordinary diet for six months before repeating the test a little risky Many clinicians would prefer to restrict the diet to a certain extent and repeat the test in three months or sooner The diet scheme remains unaltered and still starts with a period of fasting which may last for four days on occasion If sugar is still present, insulin is then started The subsequent stages of the diet are designed to increase the carbohydrate value daily until the diet, on the fifteenth day, contains 49 g of carbohydrate, 52 g of protein, and 117 g of fat; caloric value 1460 If this amount of food satisfies and the blood-sugar is normal no insulin is given and the diet is kept at this level for many months Dr Leyton does not mention the alternative method of treatment with a maintenance diet of about the same value as that of his fifteenth day There are two schools in England, just as there are in the United States, and Dr Leyton belongs to the one which believes that a short period of under-nutrition increases the chance of recovery of sugar tolerance much more than the alternative method He also never uses the high carbohydrate and high insulin treatment advocated by some writers The rules for the administration of insulin are clearly set out A knowledge of the blood-sugar is very important, and as it is often difficult for patients who live away from laboratories to have this estimated, Dr Leyton is accustomed to teach patients how to do this by Folin and Wu's method The index is adequate The food tables are sufficiently detailed for most patients

---

Recent Advances in Hæmatology.

By A. PINEY, M D , Research Pathologist, London Cancer Hospital London J and A. Churchill 1927 Pp 272 12*s* 6*d*

IN his introduction the author describes hæmatology as "that branch of biological science which deals with the morphology of the blood and blood-forming tissues" Hæmatology as thus defined is a subject of which it is difficult to describe the recent advances, on account of their extreme paucity Almost the only section of the volume containing matter that falls strictly under this head is that concerning the hæmorrhagic diatheses In the knowledge, and to a less extent in the treatment of these conditions, notable advances have been made in the past few years, and these are adequately summarised by Dr Piney. This is the first volume to appear in this country in which a serious attempt has been made to bring together the recently won knowledge on the subject It is a matter for regret that considerations of space did not permit an even more extensive excursion into this field The one other direction in which notable advance has been made in the knowledge of the blood, that of the blood groups and their significance, has not been regarded by the author as coming within the scope of the work A section on this subject would, however, have greatly enhanced its value For the rest this volume follows in a competent manner the usual lines of text-books on the morphology of the formed elements of the blood and of the blood-forming tissues, and is a useful and complete compendium of the present state of knowledge on this subject

---

Pathological Micro-organisms of the Eye

Die pathogenen Mikro-organismen des Auges By Prof. Dr F v HERRENSCHWAND Berlin and Vienna Urban and Schwarzenberg 1927. With 17 illustrations and 12 coloured plates. Pp 310 M 24

DR Axenfeld's work on the Bacteriology of the Eye came out in 1908, and was at once translated into English by Angus McNab, one of the early victims of the war Prof Herrenschwand does not desire to compete with that work, but to provide one which shall prove supplementary to it and to bring the subject up to date The scheme of his book differs somewhat from that of Axenfeld's After an introductory chapter on the general morphology of pathogenic bacteria, each organism pathogenic to the eye is dealt with fully, including its relation to other pathological conditions both of men and of animals ; the results of injections of the organism into animals are described, and the diseases of the eye which it is liable to cause in man are stated A bibliography of the literature bearing on each micro-organism in turn is appended, and since this is brought up to the end of 1926, it should prove especially valuable If we may select one section of the book as of peculiar importance it is that dealing with the recent work on *Spirochæta pallida* In an appendix directions are given for the collection of material from the eye, and for methods of staining, cultivation, and inoculation. The 12 coloured plates, each with from four to seven reproductions of drawings from stained specimens, leave nothing to be desired

The work will be valued in every library attached to a pathological ophthalmic department

---

Mind and Personality

By WILLIAM BROWN, M D , M R C P , D Sc , Wilde Reader in Mental Philosophy, Oxford London : University of London Press 1926. Pp 354. 12*s* 6*d*.

DR. Brown's readable volume can only be treated with justice if it is regarded as a collection of essays rather than a work with a unified thesis. That the author has a point of view we have little doubt But it is due to a philosophic attitude rather than a scientific detachment which finds a thesis from the examination of data of experience Philosophy rather than psychology seems to be the author's pursuit He appears to be bothered by the universe rather than curious about it In scanning a wide cultural horizon for some philosophic resting-place he pauses from time to time to quarry in the strata of the human mind, but his researches are always metaphysically coloured. This by no means detracts from the interest of the volume before us It gives everything with which he deals a background against which empirical data derived from experimental psychology and clinical psychology are thrown into relief and acquire a value and a meaning which, if a little alien to the detached method of science, will prove satisfying and restful to those of us who, immersed in the welter of discrete facts, find solace in the unifying value of philosophy Philomany people of undoubtedly unsound mind who can be brought back within a very short while if suitably treated Should certification be delayed on this account, it is as well to secure the support of another doctor for the delay, and to place the facts before the Board of Control

Two facts that stood out in his experience of drug addiction, said Dr Fothergill, were that, apart from alcoholism, it is found only amongst intellectuals, and that without corroborative evidence nothing the patients say is to be relied on A voluntary addict, without disease or injury as the excuse, must be regarded as having been potentially mentally unbalanced If this is accepted, then treatment will follow on similar lines to that for mental exhaustion, as it would be useless to treat the drug addiction without treating the underlying cause Drug addiction as the result of disease or injury becomes increasingly difficult to treat when the physical reasons for giving the drug are gone Where there is no disease or injury, the treatment is by tapering—in the case of alcohol, at the commencement, with morphia and its derivatives, at the end It must be certain that no drugs can reach the patient without knowledge of the attendant or the doctor The amount of liquid in the barrel of the syringe, or the size of the suppository, must never be varied As the treatment progresses, and the strength of the dose is decreased, it must be anticipated that the patient will become more difficult to handle

Reviews and Notices of Books.

SECRETION OF THE URINE

Second edition By A R CUSHNY, M A, M D, LL D, F R S, late Professor of Materia Medica and Pharmacology in the University of Edinburgh. London Longmans, Green and Co, Ltd 1926 Pp 283 16*s*

ONLY those who have worked on the problem of urinary secretion are in a position adequately to assess their debt to the author of this monograph The first edition, which appeared in 1917, proved a monumental landmark, for before its advent the masses of uncorrelated facts had merely led to a chaos of hypothesis and misrepresentation The value of a scientific theory is not to be reckoned entirely by its power to explain the experimental facts elicited in the past, but also by the extent to which it can be readily modified in order to bring it into line with the latest established facts Cushny's theory of the mechanism of the secretion of urine illustrates these desirable qualities to a high degree

In this edition further evidence in favour of filtration as being the function of the glomeruli is included, emphasis being laid on the experiments of Wearn and Richards in the frog and on those of Starling and Verney, who used the heart-lung-kidney preparation in the dog Cushny originally imputed to the tubules the simple function of reabsorbing a fluid of unvarying composition from the glomerular filtrate, this fluid being an optimal fluid and presumably resembling Locke's fluid in its composition The theory of reabsorption by the tubule cells has been strengthened by recent work both in the case of the frog and in that of the mammal, but the original conception by the author of the simplicity of composition of the fluid reabsorbed is no longer in accordance with the experimental facts A comparison of the concentration ratios of, for example, urea and sulphate in plasma and urine shows that that of sulphate is higher than that of urea Urea therefore cannot be regarded as a no-threshold substance Such observations necessitate a change in our conception of the nature of the reabsorbed fluid, so that we now look upon this fluid as containing the following substances water and glucose; chloride and bicarbonate; potassium, urea, and urate; phosphate, sulphate, creatinin, and foreign substances—the degree to which each of these substances is reabsorbed varying inversely with its position in the group, that is to say, water and glucose show the highest degree of reabsorption, creatinin the lowest

The "modern theory of urinary secretion," originally outlined by Cushny, has thus been slightly modified to conform to the facts elicited by recent researches In its present form it retains the valuable qualities of simplicity of conception and of incentive to further work and can best be studied in the monograph prepared by Prof Cushny before his death

---

SEMILUNAR CARTILAGES OF THE KNEE

Pathologie des Menisques du Genou. Par ALBERT MOUCHET, Chirurgien des Hôpitaux de Paris, et LOUIS TAVERNIER, Professeur agrége à la Faculté de Médecine de Lyon, Chirurgien des Hôpitaux. Paris Masson et Cie 1927 Pp 98 Fr 18

THIS monograph embodies the report on the subject presented by the authors to the thirty-fifth French Congress of Surgery, which met at Paris in 1926 Internal derangement of the knee-joint has for many years been a familiar subject of discussion in this country, and later in America, but in France it has attracted little attention till recently, possibly the vogue of football in that country has drawn attention to it, although, as is well known, such injuries as displacement of a knee cartilage are common among miners in all countries

After shortly describing the normal anatomy of the parts concerned, the authors turn to pathological anatomy and describe the lesions which most generally are found after injury As to traumatic meniscitis, described by Roux, of Lausanne, the authors conclude that it is not a pathological reality, and that the changes found do not concern the fibrocartilages themselves They hold the view that rotation of a flexed knee is not necessarily one of the causes of damage to the cartilages, for they have recorded cases in which simple forcible extension without rotation has produced rupture of a meniscus The determining cause, in their opinion, is some interference with free movement between condyle and fibrocartilage Among secondary complications they mention loose bodies, dry arthritis, and injury to ligaments They are agreed with previous observers as to the preponderating frequency of injuries of the internal cartilage After considering the claims of Roux to have cured "meniscitis" by massage, the authors dispute, as aforesaid, the existence of this lesion, and hold that Roux's cases were really those of limited tearing of a cartilage, which cannot be cured by massage Meniscopexy or fixation of the torn cartilage is dismissed in a few words as useless ' The operation of arthrotomy for removal of torn cartilages, which the authors favour, is one by a transverse incision which no doubt gives a better view of the interior of the joint than does a longitudinal one, but which, as described by them, involves division of one of the lateral ligaments of the joint The importance of early active movements after operation, in order to prevent stiffness, is properly emphasised Proper caution is advocated in cases in which the symptoms are equivocal, many of these clear up without arthrotomy, showing no rupture of a cartilage

The last few pages are devoted to consideration of cysts of the cartilages Such cysts are almost entirely confined to the external cartilage Excision of the cartilage and cyst is the *only proper treatment* The book is well illustrated with 26 figures, most of which are semidiagrammatic drawings, which are better than photographs for their purpose It should be of value in France, where monographs on the subject are rare, but in this country, where so much has been done and written in the surgery of the knee-joint, it is less likely to attract attention.

THE LANCET.

ONDON, SATURDAY, JUNE 18, 1927.

ATH CERTIFICATION UNDER THE NEW ACT.

EN the Births and Deaths Registration Act 26 comes into operation on July 1st it will *two important purposes* The first of these is rotection of the community from crime. The f 1874 left certain loopholes which required to opped up The registrar s certificate or the ers order was sufficient authority for burial, t did not always follow that either of these nents was actually produced; it remained tly legal for a burial to be conducted without n authority provided that the registrar was ed after the ceremony The new Act prohibits al of the body except upon the registrar's cate or coroner s order, and it sets up a system interchecking which should make it impossible document authorising the burial of one person used for the burial of another or for the burial of notified person to be carried out without the rar s knowledge Further, by requiring the ration of stillbirths and by insisting that for purpose information shall be furnished under n specified heads, the new Act should prevent burial of children as stillborn when in fact were born alive, but their lives were taken ly after birth Another new provision is that requires the medical practitioner to send the certificate direct to the registrar instead of ing it to a relative, the latter practice being ed to have enabled unscrupulous persons to ertificates for improper purposes Finally, the Act empowers the Minister of Health (with oncurrence of the Home Office) to make regulafor the following matters The Minister may ibe the period and form of notice to be given e coroner before a body is removed out of and, he may impose conditions and restrictions embalming and upon the disposal of bodies wise than by burial or cremation—for example, l at sea, he may also regulate the period of a body may be retained after death in an nted house or other premises The regulations under this power have not yet been published. anwhile the Registrar-General has been bringing own regulations up to date by making a lidated set governing the registration of births, irths, deaths and marriages, the re-registration e birth of legitimated persons, and the appropriate in the case of adopted children. The Registrarral s regulations do not much concern the medical tioner; the latter will, however, bear in mind new duty (already mentioned) of delivering t to the registrar every certificate of the cause of . Registrars will furnish practitioners with a of officially franked envelopes for the posting of the certificates, and also with a stock of medical certificate books Each form in these books is a threefold document At the outer side there is the detachable form of notice on which the practitioner, after signing a certificate of the cause of death, must give written intimation of the fact of signing to the relative or other person liable to act as informant of the death for registration purposes Adjoining this form of notice comes the form of medical certificate itself The rest of the page consists of a counterfoil for the use of the medical practitioner which he is advised to fill up in all cases The counterfoil, the medical certificate, and the notice of signing will all bear the same serial number in the case of each particular death, and will thus provide an easy method of connected reference

The second purpose of the new Act is the compilation of more accurate medical statistics. During the half century or so since the Births and Deaths Registration Act of 1874 came into force, the form of the medical certificate of the cause of death has remained almost unaltered. The modification in the "Y" series of books, issued in the autumn of 1924, cleared up certain ambiguities which in practice were found to attach to the old form, but retained its essential characters The contents of the certificate have now undergone radical revision after consultation with persons representing the leading bodies in the medical profession Emphasis is again laid on the desirability of employing as far as possible only such terms to describe the cause of death as are recognised in the nomenclature of the Royal College of Physicians of London, there should be no hesitation in complying with this very reasonable wish expressed by the Registrar-General. But the difficulty of exact statement has arisen and will still arise where the practitioner in attendance during the last illness is unable to ascribe the death to a single cause, the distinction to be drawn between "primary," "secondary," and "contributory" on the existing certificate has always been found difficult to interpret, and the new form has been designed to avoid this difficulty and to make the official records of the causes of death a more exact summary of the opinions expressed in the certificate than hitherto To this end the new form of certificate is divided into two sections In the first section is to be entered the immediate cause of death as well as any morbid condition or conditions which led up to it the latter being stated in order backwards from the immediate to the remoter causes In the second section are to be entered conditions not in the immediate chain of pathological events which have led to death but which have none the less contributed seriously to the fatal issue Examples appended to the medical certificate book serve to make these points clear, they are reproduced along with a facsimile of the new certificate itself on p 1314 of our present number. Although provision is thus made for a series of entries, the Registrar-General begs the practitioner in each case to consider whether the essential features cannot be epitomised by statement of a single cause The practitioner's attention is also called to the form of certification desirable in the case of deaths from cancer, childbirth, violence, or anæsthetics, and an entry on the back of the certificate form indicates to the Registrar-General whenever the practitioner is in a position to give him additional information later as to the cause of death, for the purpose of more precise statistical classification There is no doubt that in its new form the death certificate is likely to serve its many and varied purposes better than any which has previously been devised.

sophically Dr Brown is deeply indebted to Bergson—a philosopher who in many ways has done as much for the affective life in philosophy as Freud has done for it in psychology There are essays of course dealing with subjects of practical psychological significance, and some of them form excellent epitomes of recent work in particular fields For example, the chapter on Mind and Experimental Methods will be to the beginner a very valuable survey of the introduction of laboratory methods into psychology, and here the author speaks as one in authority The chapter on Mathematical Ability is equally good Dr Brown gives us of his experiences in the psychopathological field, and while distinctly impressed by the psycho-analytic approach is by no means carried away He is to be congratulated on having been deeply analysed without suffering a scorch mark in the passage through the fire—he found his religious attitude remained unchanged In our experience this is rare

Dr Brown's volume will be a stimulus to those who are not actually engaged in psychopathology and a pleasant interlude to the specialist who needs a little philosophic leaven added to his occasionally arid researches

MEDICAL DIATHERMY.

Leitfaden der Diathermiebehandlung By A Laqueur, Medical Director of the Hydrotherapeutic and Mechanotherapeutic Institute of the Rudolf Virchow Hospital, Berlin. Berlin S Karger 1926 Pp 134 M 4 80

Die Klinische Anwendung der Diathermie By Dr Iwan von Buben, Assistant in the Frauenklinik of the University of Budapest With a foreword by Prof Dr Bela v Kelen, Director of the Rontgen Institute of the University of Budapest Leipzig Johann Ambrosius Barth 1926 With 85 illustrations Pp 175 M 11.40

Anleitung zur Diathermiebehandlung Second edition By Dr G Bucky Berlin Urban and Schwarzenberg 1927 With 132 illustrations Pp 200 M 6

A good impression of the extent of the therapeutic field of medical diathermy and the progress that has been made by German and Austrian specialists in the subject is conveyed by three books published in Berlin and Leipzig during the last year. In all of them brief introductory accounts are given of high-frequency currents and the relevant physical principles The path and distribution of these currents in various conductors and methods of applying them to different regions of the body are described The action of the diathermy current on the body in health and in disease is shown, and the subject of dosage is considered The maladies which respond to diathermy and methods of applying the treatment are discussed under the headings of the different systems and regions of the body, surgical diathermy being less fully considered than medical diathermy Dr von Buben devotes only 22 pages to it, while the other authors give mere introductory outlines

Dr von Buben speaks highly of the value of diathermy in gynæcology, particularly in cases of chronic infection of the uterus and urethra and of the pelvic supporting tissues In the treatment of sciatica he describes a method in which three electrodes are applied respectively to the back of the hip, front of the thigh just above the knee, and to the middle of the leg These electrodes are connected to the three terminals of the diathermy machine He seems to think that better results are obtained when the whole length of the nerve is subjected to diathermy than when the treatment is applied to the regions to which the pain is referred Dr von Büben's book is clearly printed in large type and has a number of useful illustrations

Dr Laqueur's book, smaller in size and with fewer pictures, will be a useful guide to those who wish to learn the essentials of the subject The author describes some interesting experiments which h conducted in order to show the influence of diatherm on organisms introduced into the knee-joints of dogs He showed that organisms such as the cholera vibrio the pneumococcus, and the gonococcus, which ar sensitive to moderate degrees of heat, were eithe destroyed or rendered much less virulent afte diathermy had been applied to the joints, while th temperature reached did not damage the tissues of th host

Dr Bucky's book is an enlarged edition of a worl written as long ago as 1911 , it contains a number o useful line drawings which show the position of th electrodes for the treatment of different regions Under the headings of various diseases the autho describes, in tabular form, the method of action of th diathermy, the course of the disease and the results o the treatment, the method of application of th current, and the frequency Of special interest is th so-called " alternator " devised by Dr Bucky him self By its means the operator is able to direc the current through regions by the " cross-fire ' method In this way a greater degree of heat may b obtained in deep regions without undue heating of th superficial tissues Dr Bucky also describes hi " pulsator " By means of this instrument the curren is made to oscillate intermittently The autho believes that better results can sometimes be obtaine when this instrument is used Dr Bucky call attention to a curious and uncommon form of bur which may be caused in the subcutaneous fat whe the diathermy current is passed through the sk and superficial fascia Fat offers a much highe resistance to the current than the skin and can b damaged by a diathermy current which is insufficien to harm the skin.

The books by Bucky and von Buben contain, i index form, abundant references to the literature o medical diathermy

SCIENCE AND RELIGION

The Creator Spirit By C E Raven, D D Canon of Liverpool London Hopkinson an Co. 1927. Pp 310 8s 6d

There have been a number of books and paper lately about science and religion This one strike us as one of the best and most helpful, especially fo those who are not very deeply trained in technica philosophy It is based on Hulsean lectures given i Cambridge, England, and Noble lectures in Cambridge Mass , and Canon Raven brings into the discussion range of knowledge in history, theology, philosophy and biology which is an admirable equipment for hi active churchmanship He adds, too, the specia qualification of being a good field naturalist, and draw many illustrations from his personal knowledge o birds and moths—a line of study which brings ou clearly the problems which biology has to solve if i does not do very much to solve them Broadl speaking, the author is an emergent evolutionist wh rejects altogether the probability of any dualisti interpretation of human experience Religion is a imperfect explanation in so far as it fails to explai the fields which have been specially explored b naturalists , the scientific account of the world fail by as much as it excludes religious data Evolutio has proceeded in one continuous series from th electron, through atoms, molecules, substances, lif intelligence, *spirit, to the saint* which is the culmina tion that we can at present apprehend ; it has happene neither by luck nor cunning but by the love of Go Canon Raven assumes as axiomatic what is funda mental to the Christian position ; he states the ca against Darwinism too emphatically ; the discussio comes, as it seemingly must always come, to poin which are self-evident to one mind and incomprehe sible to another But the whole is a sincere and ab attempt to achieve progress in a line where progre at last seems possible, and where it would be welcom by at least as many naturalists as theologians commend it heartily

THE LANCET.

ONDON, SATURDAY, JUNE 18, 1927.

ATH CERTIFICATION UNDER THE NEW ACT

EN the Births and Deaths Registration Act 26 comes into operation on July 1st it will two important purposes The first of these is rotection of the community from crime The t 1874 left certain loopholes which required to opped up The registrar's certificate or the r's order was sufficient authority for burial, , did not always follow that either of these ients was actually produced, it remained tly legal for a burial to be conducted without n authority provided that the registrar was d after the ceremony The new Act prohibits al of the body except upon the registrar's cate or coroner's order, and it sets up a system nterchecking which should make it impossible document authorising the burial of one person used for the burial of another or for the burial of notified person to be carried out without the 'ar's knowledge Further, by requiring the ation of stillbirths and by insisting that for urpose information shall be furnished under n specified heads, the new Act should prevent urial of children as stillborn when in fact were born alive, but their lives were taken r after birth Another new provision is that requires the medical practitioner to send the certificate direct to the registrar instead of ng it to a relative, the latter practice being ed to have enabled unscrupulous persons to rtificates for improper purposes Finally, the Act empowers the Minister of Health (with ncurrence of the Home Office) to make regula- for the following matters The Minister may ibe the period and form of notice to be given coroner before a body is removed out of nd, he may impose conditions and restrictions embalming and upon the disposal of bodies ise than by burial or cremation—for example, at sea, he may also regulate the period of a body may be retained after death in an ted house or other premises The regulations under this power have not yet been published nwhile the Registrar-General has been bringing wn regulations up to date by making a dated set governing the registration of births, ths, deaths and marriages, the re-registration birth of legitimated persons, and the appropriate n the case of adopted children The Registrar- l's regulations do not much concern the medical ioner, the latter will, however, bear in mind w duty (already mentioned) of delivering to the registrar every certificate of the cause of Registrars will furnish practitioners with a of officially franked envelopes for the posting of the certificates, and also with a stock of medical certificate books Each form in these books is a threefold document At the outer side there is the detachable form of notice on which the practitioner, after signing a certificate of the cause of death, must give written intimation of the fact of signing to the relative or other person liable to act as informant of the death for registration purposes Adjoining this form of notice comes the form of medical certificate itself The rest of the page consists of a counterfoil for the use of the medical practitioner which he is advised to fill up in all cases The counterfoil, the medical certificate, and the notice of signing will all bear the same serial number in the case of each particular death, and will thus provide an easy method of connected reference

The second purpose of the new Act is the compilation of more accurate medical statistics During the half century or so since the Births and Deaths Registration Act of 1874 came into force, the form of the medical certificate of the cause of death has remained almost unaltered The modification in the "Y" series of books, issued in the autumn of 1924, cleared up certain ambiguities which in practice were found to attach to the old form, but retained its essential characters The contents of the certificate have now undergone radical revision after consultation with persons representing the leading bodies in the medical profession Emphasis is again laid on the desirability of employing as far as possible only such terms to describe the cause of death as are recognised in the nomenclature of the Royal College of Physicians of London, there should be no hesitation in complying with this very reasonable wish expressed by the Registrar-General But the difficulty of exact statement has arisen and will still arise where the practitioner in attendance during the last illness is unable to ascribe the death to a single cause, the distinction to be drawn between "primary," "secondary," and "contributory" on the existing certificate has always been found difficult to interpret, and the new form has been designed to avoid this difficulty and to make the official records of the causes of death a more exact summary of the opinions expressed in the certificate than hitherto To this end the new form of certificate is divided into two sections In the first section is to be entered the immediate cause of death as well as any morbid condition or conditions which led up to it, the latter being stated in order backwards from the immediate to the remoter causes In the second section are to be entered conditions not in the immediate chain of pathological events which have led to death but which have none the less contributed seriously to the fatal issue Examples appended to the medical certificate book serve to make these points clear, they are reproduced along with a facsimile of the new certificate itself on p 1314 of our present number Although provision is thus made for a series of entries, the Registrar-General begs the practitioner in each case to consider whether the essential features cannot be epitomised by statement of a single cause The practitioner's attention is also called to the form of certification desirable in the case of deaths from cancer, childbirth, violence, or anæsthetics, and an entry on the back of the certificate form indicates to the Registrar-General whenever the practitioner is in a position to give him additional information later as to the cause of death, for the purpose of more precise statistical classification There is no doubt that in its new form the death certificate is likely to serve its many and varied purposes better than any which has previously been devised sophically Dr Brown is deeply indebted to Bergson—a philosopher who in many ways has done as much for the affective life in philosophy as Freud has done for it in psychology There are essays of course dealing with subjects of practical psychological significance, and some of them form excellent epitomes of recent work in particular fields For example, the chapter on Mind and Experimental Methods will be to the beginner a very valuable survey of the introduction of laboratory methods into psychology, and here the author speaks as one in authority The chapter on Mathematical Ability is equally good Dr Brown gives us of his experiences in the psychopathological field, and while distinctly impressed by the psycho-analytic approach is by no means carried away He is to be congratulated on having been deeply analysed without suffering a scorch mark in the passage through the fire—he found his religious attitude remained unchanged In our experience this is rare

Dr Brown's volume will be a stimulus to those who are not actually engaged in psychopathology and a pleasant interlude to the specialist who needs a little philosophic leaven added to his occasionally arid researches

---

MEDICAL DIATHERMY.

Leitfaden der Diathermiebehandlung By A LAQUEUR, Medical Director of the Hydrotherapeutic and Mechanotherapeutic Institute of the Rudolf Virchow Hospital, Berlin. Berlin S Karger 1926 Pp 134. M 4 80

Die Klinische Anwendung der Diathermie By Dr IWAN VON BUBEN, Assistant in the Frauenklinik of the University of Budapest With a foreword by Prof Dr BELA V KELEN, Director of the Rontgen Institute of the University of Budapest Leipzig Johann Ambrosius Barth 1926 With 85 illustrations Pp 175 M 11 40

Anleitung zur Diathermiebehandlung Second edition By Dr G BUCKY Berlin Urban and Schwarzenberg 1927 With 132 illustrations Pp 200. M 6

A GOOD impression of the extent of the therapeutic field of medical diathermy and the progress that has been made by German and Austrian specialists in the subject is conveyed by three books published in Berlin and Leipzig during the last year In all of them brief introductory accounts are given of high-frequency currents and the relevant physical principles The path and distribution of these currents in various conductors and methods of applying them to different regions of the body are described The action of the diathermy current on the body in health and in disease is shown, and the subject of dosage is considered The maladies which respond to diathermy and methods of applying the treatment are discussed under the headings of the different systems and regions of the body, surgical diathermy being less fully considered than medical diathermy Dr von Buben devotes only 22 pages to it, while the other authors give mere introductory outlines

Dr von Büben speaks highly of the value of diathermy in gynæcology, particularly in cases of chronic infection of the uterus and urethra and of the pelvic supporting tissues In the treatment of sciatica he describes a method in which three electrodes are applied respectively to the back of the hip, front of the thigh just above the knee, and to the middle of the leg These electrodes are connected to the three terminals of the diathermy machine He seems to think that better results are obtained when the whole length of the nerve is subjected to diathermy than when the treatment is applied to the regions to which the pain is referred Dr von Buben's book is clearly printed in large type and has a number of useful illustrations

Dr Laqueur's book, smaller in size and with fewer pictures, will be a useful guide to those who wish to learn the essentials of the subject The author describes some interesting experiments which h conducted in order to show the influence of diatherm on organisms introduced into the knee-joints of dog. He showed that organisms such as the cholera vibri the pneumococcus, and the gonococcus, which ar sensitive to moderate degrees of heat, were eith destroyed or rendered much less virulent aft diathermy had been applied to the joints, while th temperature reached did not damage the tissues of th host

Dr Bucky's book is an enlarged edition of a wor written as long ago as 1911 , it contains a number o useful line drawings which show the position of th electrodes for the treatment of different region Under the headings of various diseases the autho describes, in tabular form, the method of action of th diathermy, the course of the disease and the results o the treatment, the method of application of th current, and the frequency Of special interest is th so-called " alternator " devised by Dr. Bucky himself By its means the operator is able to direc the current through regions by the " cross-fire method In this way a greater degree of heat may b obtained in deep regions without undue heating of th superficial tissues Dr. Bucky also describes hi " pulsator " By means of this instrument the curren is made to oscillate intermittently The autho believes that better results can sometimes be obtaine when this instrument is used Dr Bucky cal attention to a curious and uncommon form of bur which may be caused in the subcutaneous fat whe the diathermy current is passed through the sk and superficial fascia Fat offers a much highe resistance to the current than the skin and can b damaged by a diathermy current which is insufficien to harm the skin

The books by Bucky and von Buben contain, i index form, abundant references to the literature o medical diathermy.

SCIENCE AND RELIGION

The Creator Spirit By C E RAVEN, D D Canon of Liverpool London Hopkinson an Co 1927. Pp 310 *8s 6d*

THERE have been a number of books and pape lately about science and religion This one strike us as one of the best and most helpful, especially fo those who are not very deeply trained in technica philosophy It is based on Hulsean lectures given i Cambridge, England, and Noble lectures in Cambridg Mass , and Canon Raven brings into the discussion range of knowledge in history, theology, philosophy and biology which is an admirable equipment for hi active churchmanship He adds, too, the speci qualification of being a good field naturalist, and draw many illustrations from his personal knowledge birds and moths—a line of study which brings ou clearly the problems which biology has to solve if does not do very much to solve them Broad speaking, the author is an emergent evolutionist wh rejects altogether the probability of any dualist interpretation of human experience Religion is imperfect explanation in so far as it fails to expla the fields which have been specially explored naturalists ; the scientific account of the world fa by as much as it excludes religious data Evolutio has proceeded in one continuous series from th electron, through atoms, molecules, substances, li intelligence, spirit, to the saint which is the culmin tion that we can at present apprehend , it has happen neither by luck nor cunning but by the love of Go Canon Raven assumes as axiomatic what is fund mental to the Christian position ; he states the ca against Darwinism too emphatically , the discuss comes, as it seemingly must always come, to poi which are self-evident to one mind and incompreh sible to another But the whole is a sincere and a attempt to achieve progress in a line where progr at last seems possible, and where it would be welcon by at least as many naturalists as theologians commend it heartily

But perhaps he hardly lays sufficient emphasis on the distaste for vaginal examination, shared by patient and doctor, which has a doubly injurious effect. Not only has the practitioner who relies on the patient's report only the vaguest idea of the general condition of her genital canal, but the fact that in this country at least a vaginal examination is so seldom part of a routine overhaul makes it more difficult for a doctor to insist on it without unduly alarming a patient if slight irregularities of menstrual bleeding should occur. In the discussion on Prof. EWING's paper, Dr. H. R. CHARLTON said that he had noted the number of women out-patients suffering from cervicitis who had derived no benefit from such treatment as had previously been suggested to them, and he proposed the formation of a cervical cancer committee to devise a proper therapy for the inflamed cervix, to be followed by a vigorous campaign among women in favour of "pelvic prophylaxis." This suggestion deserves serious consideration. Prof. EWING also drew the attention of dentists to the intra-oral group of cancers, and urged the need of a higher standard of buccal cleanliness. Since in spite of many formidable efforts no discovery of an effective bactericidal agent had ever been made, he advocated the regular use of soap gargles and mouth-washes. Circumcision, attention to the cleansing of the skin in those who have oily skins and heavy growths of coarse hair, the avoidance of habitual abuse of the stomach and of stagnant secretions in the breast are among the ways in which he suggests the incidence of cancer may be lessened. He is hopeful that future research will add considerably to this list, and that when other means of prevention become widely known cancer may become the eliminator of the unwary, the unintelligent, and the unfit.

It is in this direction that an optimistic outlook should be directed, for Prof. EWING's concluding remarks, quoted with approval in the course of the discussion by Prof. DEELMAN, are less cheerful in tone. These two authorities agree first that it appears more and more evident that early diagnosis alone is not capable of accomplishing the desired reduction in the death-rate, and secondly that the list of cancers incurable from their first beginnings is a long one. Prof. EWING points out that the experience of patients accomplishing a cure of early cancer is usually a severe one, while the fate of the failures is passed over in silence. The public knows these facts, and therefore any plan of squarely meeting the problem of cancer control must eventually lean heavily upon cancer prevention. Prof. CLAUDE REGAUD, who was one of the many guests to join in a warm appreciation of Prof. EWING's survey, interpreted this conclusion in the sense that it is to laboratory researches rather than to statistics and clinical observations that we must look for further progress. Pathological histology, he holds, lies at the bottom of all classifications that we make, plays a preponderant rôle in diagnosis, and has, moreover, become the indispensable guide of all those, like himself, who devote themselves to the problem of the biological action of radiations. It is gratifying to hear these views expressed by authorities whose work is done in countries where the proportion of energy and money spent on propaganda rather than research is much greater than in our own. The attitude in this matter taken up by those who direct our imperial funds and campaigns is not only well adapted to our national psychology, but is supported by workers who have the best opportunities of critically estimating the directions in which progress is to be expected.

PRACTICE ABROAD

THE General Medical Council has just issued a revised edition of the useful booklet,[1] compiled by its Registrar, Mr. NORMAN C. KING, which informs practitioners both at home and abroad what are the conditions under which they may practise in countries other than those in which they obtained their qualifications. Since 1921, when the report was last issued, the Treaty of Versailles has altered substantially the map of Europe, and with it many of the local ordinances of medical and dental practice. The formalities with which a foreign medical diplomate must comply in the various countries of the world vary from none at all up to the most onerous and exclusive rules. In the first category the Registrar has drawn up a table of countries or states in which persons may practise without a legal qualification of any sort. A close study of this table is very entertaining. Mr. KING remarks on the limited number of these countries, but the list includes Great Britain and its associated Dominions, Germany with Danzig, the Scandinavian peninsula, some of the central United States of North America, and a motley of lands at a low level of civilisation such as Abyssinia, Albania, Arabia, China, and Siam. There is no Latin country in this list, and one cannot help feeling that in many of the countries inhabitants may be well able to repel the foreign medical invader without statutory assistance. The appearance of Germany in the list will surprise some people; in that country not only is there no embargo on unqualified persons, but medical practice is as free as the author of "Rab and his Friends" could have wished it. This freedom is not new; both before and since the war foreigners with or without foreign qualification have been at liberty to practise in the Reich, provided that they do not describe themselves as physicians, surgeons, oculists, accoucheurs, and the like. An Englishman may, for example, style himself "physician legally admitted in England." There are, Mr. KING states, only a few exceptions from this rule. Although Great Britain is on the free list for medicine it has of course recently been removed from it for dentistry, and we may add, for midwifery. The very large majority, however, of the 207 countries or states named in the report prohibit unqualified persons from practice, with here and there some curious exceptions. In British Guiana they are tolerated in any district which does not possess a registered practitioner. In Ontario and in certain of the North American States osteopaths, chiropractors, and the like are allowed to practise within certain limits; in Connecticut members of these cults are not permitted to administer drugs or perform surgical operations. The Mexican Congress is on the brink of making some decision on the subject. In Colombia an unqualified person can in certain circumstances obtain permission to practise medicine but not surgery. In Ceylon native practitioners, called vedaralas, are allowed to practise for gain but practitioners of Western medicine are not allowed to do so unless they are registered, although an osteopath is left unmolested in his claim to treat diseases such as malaria if he does not write prescriptions for internal use.

---

[1] Report as to the Conditions under which Medical and Dental Practitioners registered or legally qualified in their own country, may practise abroad. Sixth edition. Constable and Co., 10, Orange-street, London, W.C. 1927. 2s. 6d. (Post free U.K., 2s. 9d.; Colonies, 3s.; Abroad, 3s. 3d.)

THE PSYCHOLOGY OF CANCER CONTROL

The rather meagre reports hitherto received[1] in this country of the international cancer symposium, held at Lake Mohonk in September last under the auspices of the American Society for the Control of Cancer, are now amplified by the full proceedings These are published as an extra number of *Surgery, Gynecology, and Obstetrics*,[2] the cost being borne by the Harry M Lasker Memorial Fund It will be remembered that the conference was called for the purpose of considering the prevention and cure of cancer from a practical standpoint, and of expressing in concise language the fundamental groundwork of fact and opinion upon which the collective effort now being made in the United States and other countries for the control of cancer should be continued and extended Over 100 persons were present, and the large majority of these were not delegates but individuals invited because of their personal distinction in some aspect of cancer control Among the 16 European guests were four from Great Britain, being Mr Sampson Handley, Dr A Leitch, Dr J A Murray, F R S, and Sir John Bland-Sutton, the last named being privileged to respond to the friendly greeting extended by Prof W H Welch to the foreign guests and to give the opening address in the executive sessions

As a preliminary to further discussion, the efforts now being made in each country represented were described These accounts, given in turn by Mr Sampson Handley (England), Prof H Hartmann, Prof L Bérard, and Prof T Marie (France), Prof C Du Bois and Dr A Reverdin (Switzerland), Prof J Maisin (Belgium), Prof J Fibiger (Denmark), Prof R Bastianelli (Italy), Prof F Blumenthal and Dr R Bierich (Germany), and Mr G A Soper, Dr J C Bloodgood, Dr H C Saltzstein (U S A) make interesting reading, for they show not so much a different level of knowledge or endeavour as an appreciation, conscious or unconscious, of the psychology of various peoples and of the means whereby the desired end can be achieved without arousing phobias or public antagonism in any country Prof H T Deelman (Holland) brought this point out clearly in discussion He said that one part of Holland was populated largely by people of precise habits, with a predisposition for exact scientific data, who readily availed themselves of any medical assistance offered to them It would be undesirable to plaster their walls with warnings to consult a doctor as soon as possible after the manifestation of any given symptom, since they would soon discover that not all the cases coming as soon as possible were cured, would resent being given false hope and would develop distrust of medical science On the other hand, the inhabitants of the southern part of Holland were more careless and superficial in their mode of life, and were inclined to place faith in quacks and marvellous cures These people felt friendly to the scientific physician but had no great respect for him Here a warning to consult him as soon as possible might produce good results, because the cure of any case of cancer would make a deep impression The psychological differences between nations were also emphasised by Mr Sampson Handley at an earlier session He explained that the principal efforts made in Great Britain had been in the direction of fostering laboratory research, and that the sporadic attempts made at popular education had been on the whole ill supported, because of a general national scepticism as to their value and advisability He held that the training of the cancer specialist, the provision of facilities for consultation with him, and the education of the practitioner were likely to be the most hopeful directions of progress in this country, to the medical profession should be entrusted the duty of instructing the mass of the profession, mainly by private influence and word of mouth, in the few essential facts about cancer which are necessary for their safety The reason why publicity methods which excite attention in other more emotional peoples make little impression in this country is that our people react well to an immediate danger but not to a contingent one The English, according to Mr Handley, are not inclined to worry about the risks of life, regarding it at best as a dangerous business, when assured that one person in seven of 30 years of age or over will die of cancer they are unperturbed, reflecting that after all favourable odds of six to one are good enough in this uncertain world ! Nevertheless, Mr Handley admitted that though the British conception of cancer control was on sound evolutionary lines, it was incomplete, and that while sensation and panic-mongering must be avoided, direct popular education on cancer by lectures and leaflets must be undertaken in order to ensure that sufferers seek early advice

To this end we may do well to search the communications read at the conference to see whether any new facts were agreed on or any fresh ideas elicited From the point of view of publicity the interesting discussions on how we should regard the new theories of the origin of cancer, opened by Prof G Roussy, on the value of statistical returns, and on the mortality from cancer of various civilised and uncivilised races, are of little concern, though no serious student of cancer can ignore these pronouncements The address by Dr W S Salzstein on newspaper publicity in cancer control gives some useful hints, though again these are not all applicable in countries other than his own He quotes an analysis of the relative space given by the papers during a "cancer week" to advance notices, to the reports of meetings held by a distinguished expert, and to the scientific data accumulated during the week in the free hospital diagnostic clinics, these last being of little "news value" Dr Salzstein gives as reliable sources of information for propaganda purposes the two handbooks issued by the American Society for the Control of Cancer and Mr C P Childe's handbook on Cancer and the Public, and notes that the article read at a previous session of the symposium by Prof J Ewing on the Prevention of Cancer forms an admirable basis This address evidently impressed the conference, and, indeed, supplies a temperate and thoughtful review of the subject Prof Ewing deplores the current neglect of the prevention of cancer and points out that a rational basis for attempts at prevention lies in the fact that the major forms of the disease are due to some form of chronic irritation All types of chronic infection and irritation should be scrutinised for their possible relation to cancer, he mentions the removal of pigmented moles and the drainage of infected antrums among the precautions less generally recognised by the profession We would add to this list the treatment of endocervicitis manifested in the chronic vaginal discharge which is so frequent a symptom and so rarely the object of careful local investigation in general practice Prof Ewing does point out the danger of neglected cervical lacerations and of an interrupted healing process after these lesions and cervical erosions test, the testing of diphtheria prophylactic, and the labelling of what is a human dose , it deals also with tuberculins and tubercle vaccines, the production of all sera from living animals, and the particular provisions as to antimeningococcus serum, antidysentery sera, and diphtheria and tetanus antitoxins The Third Schedule relates to salvarsan and its derivatives, the Fourth to insulin, and the Fifth to pituitary (posterior lobe) extract There can be little doubt that the new law will not only protect the public, but will also assist the practitioner. who has hitherto been without certainty or standardisation in administering many of the substances to which the Act applies

[2] Vol xliv, May, 1927, No 5A Publishers for Great Britain, Baillière, Tindall and Cox

The main points in which the regulations differ from those which were proposed a few weeks earlier in draft form are these. The requirement that a substance be sealed in a previously sterilised glass container before sale is relaxed where products are effectively sterilised by heat after being filled in containers There is a new Part V , relating to therapeutic substances manufactured for export only, allowing the licensing authority to dispense with the requirements of the regulations if a substance is being exported to a country where manufacture and sale are already regulated There are differences of nomenclature as to salvarsan and its derivatives Salvarsan, neosalvarsan, and sulphurosalvarsan, so named as " proper names " for labelling in the draft regulations, give way to arsenobenzene, novarsenobenzene, and sulpharsenobenzene, and the draft proposals as to silver salvarsan and neo-silver-salvarsan are changed Finally the date of operation of the regulations, which was originally proposed as August 6th next for all purposes, is varied (as already stated) by allowing a further six months' grace in respect of the regulations relating to labelling The Minister of Health announces also that he has intimated to the Association of British Chemical Manufacturers that in the initial period immediately after August 6th some latitude will be allowed so as to permit the clearance of existing stocks and to familiarise all concerned with the new requirements Constitutional purists would no doubt prefer to see the law delayed until it can be uniformly enforced, rather than to allow the Ministry to promulgate requirements with a vague intimation that the law need not at present be observed Such criticisms, however, may be waived in view of the difficulties which the Ministry experienced in getting the Act through Parliament and in view of its success in conciliating the interests affected

RHEUMATIC FEVER AS AN INFECTIOUS DISEASE

TAKING as a text A Hirsch's opinion, reached in 1864, that rheumatic fever deserves an assured place among the acute infective diseases, Dr. R M Atwater[1] has examined the mortality statistics of the United States registration area from 1900–23, and is satisfied that they afford fresh evidence of weight that " this disease is one of the communicable infections caused by a living parasite which gains access to the body from without, and which produces a disease picture in which the age, sex, seasonal, racial, and other characteristics are fixed and very close in their resemblance to the well-known epidemic diseases " Dr Atwater has made a brave attempt to extract information from data that, as he points out, obviously leave much to be desired. Frequent changes in nomenclature at uncertain dates, differences of treatment of the same data by State and Federal statistical offices, and varying precedence given to causes of death are among the difficulties with which he has had to contend Comparison with age-distribution of the mortality from rheumatic fever in England and Wales and of hospital cases in Montreal shows an excess in the proportion of deaths above 45 in the U S registration area, which suggests that many cases of chronic arthritis have been included. The excess at the older ages still existed in the latest figures quoted (1923) though to a less extent than in 1900 In spite of these defects, the U S registration area shows a consistent female excess mortality in both the white and coloured population There is also a higher mortality among the coloured than among the white, although most of the negroes live in the south where rheumatic fever is less prevalent Dr. Atwater's main argument is based on a comparison in both English and American statistics of the annual variations since 1912 in the mortality from rheumatic fever and the mortality from septicæmia, erysipelas, and puerperal septic diseases The general resemblance is closer in the data for England and Wales. From the orderliness of the sex and age curves of deaths from rheumatic fever and from their likeness to similar curves for communicable diseases—which hardly amounts to more than a restatement of the fact of orderliness—Dr. Atwater argues " a biological process going on between the host and a parasite which is affected by varying human constitution at different ages " The epidemiological facts brought out by this paper are hardly convincing enough, however, to justify his definite conclusion, quoted above, that acute rheumatic fever is one of the communicable infections caused by a living parasite which gains access to the body from without Dr. Atwater's data, like those collected in the Medical Research Council's special inquiry,[2] may be regarded as consistent with the theory of infection, but give no definite evidence that it is the true explanation of the facts

VITAMIN E.

Vitamin E, or the reproductive vitamin as it is called, has always been regarded with a degree of uncertainty, due perhaps to the prima facie improbability that there should exist a vitamin needed both by male and female for reproduction, but which does not appear to be necessary for the non-reproducing adult But just as those improbable concepts, the growth factors, have ultimately resolved themselves into dietary essentials for upkeep, as well as for growth, so perhaps the reproductive vitamin E will finally share their fate Indeed, there is some evidence already to hand that this will be the case H M Evans and his co-workers were the first to differentiate vitamin E and to describe the pathological condition to which a deficiency of it gives rise in both sexes of the rat In the female, conception takes place and gestation begins, but sooner or later the embryos die and are resorbed or sometimes aborted In the male, degeneration of the testicle takes place, which may be of varying degrees of severity, down to a complete and incurable degeneration of all the seminiferous tubules

As regards its distribution, the same workers find that vitamin E is present in a number of foodstuffs, including to a small extent butter and cod-liver oil It is abundantly present in wheat germ and its oil, as well as in lettuce, but it seems to be completely lacking in lard In wheat-germ oil the vitamin is so concentrated that a daily dose of 25 mg suffices ; the action cannot therefore be attributed to any known vitamin, such as vitamin A, which is also present to a certain extent The vitamin survives hydrogenation, as in hardened cotton-seed oil, and is regarded as fat-soluble In their last publication Evans and G O Burr suggest that there is a quantitative relation between the amount of certain fats in the diet and the amount of wheat germ which is needed to prevent sterility When 7 7 per cent of lard is incorporated in the diet 2 2 per cent of wheat germ, also incorporated is enough , but when 22 per cent of lard is used 2 6 per cent of wheat germ is not enough Butter fat does not have this effect, but it is not itself devoid of vitamin E The action cannot therefore be due simply to excessive fat intake These workers do not show, though no doubt they possess, evidence that the rats actually ate as much of the high fat diets as they

[2] THE LANCET, March 12th, pp 552 and 562.

The next category is where the right to practise is freely granted after formal proof that the applicant's name duly appears in the Medical Register, in some cases evidence of identity and of good moral character must be added. The immense region embraced by the British Commonwealth is for the most part open to the happy possessor of an U.K. registration certificate, this makes him free of India, Australia, New Zealand, South Africa, and the eastern slopes of Canada, excluding Saskatchewan and British Columbia, which have for long required a local examination, two months ago the Province of Quebec renounced reciprocity which remains for the moment one-sided. Of foreign lands, Italy and Japan alone enjoy complete reciprocity, the arrangement made with Belgium in 1915 during the period of hostilities was not confirmed at their cessation. In all other countries the existing regulations require the holder of a medical degree to pass examinations of various extent and difficulty. In France an Arts degree is very properly a necessary preliminary to the medical degree, and foreigners receive but little exemption; in Switzerland all the examinations for the federal diploma must now be taken from matriculation onwards. What penalties are exacted for defiance is not stated by the Registrar, they probably vary much in the different countries, but at one time the Swiss Federal Authority imposed a fine of 1000 francs for the first offence and for the second the same fine with extradition to the nearest frontier. A final obstacle placed in the way of medical practice by foreigners is the requirement of naturalisation. This is the case in Austria, Poland, the Balkan countries, and a number of the North American States, and Switzerland shows signs of joining the group.

The report is a compendium of accurate and interesting information, which has accumulated gradually at the Office of the General Medical Council as a result of persistent inquiry and investigation. Even those who have no present intention of leaving the country in which their qualification is obtained might well study it in order to realise the many advantages and the occasional disabilities of their position. In the case of every country or state the name of the official is given to whom request for further information should be addressed,

◆

INTERNATIONAL CONGRESS OF OTO-RHINO-LARYNGOLOGY.

In the days before the war there used to be held at intervals an International Congress of Laryngology. The last pre-war meeting was held in Berlin. Since the war this congress has not been revived, although there was a very successful Congress of Otology in Paris, under the presidency of Prof. Sebileau, in 1922. We are now glad to hear that the supporters of both these congresses have combined in launching an International Congress of Oto-Rhino-Laryngology. It will be the first of its kind and should be successful for many reasons. It will be held on the neutral soil of Denmark, Prof. Schmiegelow, the doyen of the specialty in Scandinavia, is the President, and he will be supported by a strong committee who are all well-known workers and very welcome visitors to this country. Finally, Copenhagen at the end of July in 1928—the date fixed for the congress—will be looking its best and should form a delightful meeting-ground.

Annotations.

"Ne quid nimis"

THE THERAPEUTIC SUBSTANCES REGULATIONS.

Although the Therapeutic Substances Act received the Royal Assent on August 7th, 1925, Parliament provided that the statute should not operate until a date (between one and two years later) to be fixed by Order in Council. The date thus fixed was the latest possible—namely, August 6th, 1927. Meanwhile regulations have been made by the Joint Committee under the Act, which consists of the Minister of Health as Chairman, the Secretary of State for Scotland, and the Minister of Home Affairs for Northern Ireland. These regulations will not take effect till the Act operates on August 6th, indeed that part of them which deals with labelling is not to take effect till six months later still. The regulations, dated May 31st, differ in only a few particulars (to be mentioned later) from the draft proposed by the Joint Committee which was published on April 5th. The effect of the new law is that the therapeutic substances to which the Act applies are not to be manufactured for sale without a licence. Application for such licences must be made to the "licensing authority"—in England and Wales the Minister of Health, in Scotland the Scottish Board of Health, and in Northern Ireland the Minister of Home Affairs. Applicants have to satisfy the licensing authority that they will observe various conditions in respect of adequate staff, premises, and plant, proper testing facilities, the keeping of permanent records, inspection, reports, samples, &c. A therapeutic substance advertised or sold as a proprietary medicine or contained in a medicine so advertised or sold, must be labelled with its "proper name," and must not be sold or offered for sale unless sealed in a previously sterilised glass container in such a manner as to preclude the access of bacteria. The label of the container, in addition to showing the proper name of the substance—i.e., its accepted scientific name or some name descriptive of its true nature and origin—must also give the name and address of the manufacturer, the number of his licence, a distinctive batch number, the date on which the manufacture of the batch was completed, and the nature and percentage of any added antiseptic. The label must further contain, where required, statements of minimum potency and maximum toxicity, in such cases the label must specify the date up to which the substance may be expected to retain the required potency or not to develop an excessive toxicity as the case may be, and there must be a statement of the precautions necessary for preserving the properties of the contents until that date. Sale after that date is prohibited. Schedules to the regulations prescribe the standards of strength, quality, and purity in respect of the various substances. Provision is made for testing strength, quality, sterility, and freedom from abnormal toxicity, for dealing with samples, and for preparing and using media. A special clause allows a licensee to issue a therapeutic substance to registered medical practitioners in emergency though he has no filled containers in stock, but here there are careful safeguards. Part VI of the regulations deals with licences to import substances for purposes other than scientific research, Part VII deals with research licences. The latter will contain conditions as to inspection and records and as to restriction of the particular research to specified premises, which recall the conditions under which experiments on animals are permitted. Part VIII requires that containers must be labelled "to be used solely for veterinary purposes" where the substance is intended for those purposes only. The Second Schedule has minute provisions as to the production of bacterial vaccines and vaccine lymph, the use of reagents in the Schick reflexes initiated by the birth trauma The selection of a specific manifestation might then be determined, as in Dr Strauss's cases, by psychological factors capable of elucidation and resolution by analysis

VENTILATION AND TEMPERATURE

THOUGH the need for ventilation has been recognised from remote antiquity, it is only in comparatively recent times that attempts have been made to explain it scientifically First came the belief, founded on the discoveries of Black and Lavoisier, that the harmful results of overcrowding are due to lack of oxygen and accumulation of carbon dioxide This idea, plausible as it is, was generally accepted, and has proved so tenacious that it remains the foundation upon which legislation in the textile industries is based That it is erroneous has, however, been shown by many workers, from Pettenkofer onwards, and a recent review[1] of the literature of this subject shows how far advance has been made No longer—apart from escape of poisonous fumes—is importance attached to the chemical composition of the air, measured as excess of carbon dioxide or diminution in oxygen, and no longer is it held that ill-effects arise from absorption by the lungs, to which attention was first directed by the alterations in breathing which are observed when ventilation is insufficient The organ concerned, it is now recognised, is the skin, acting through the heat-regulating mechanism of the body Hence study has been concentrated, not on the chemical composition of the air, but on its physical characteristics expressed in terms of temperature, humidity, and movement Comfort, health, and capacity for activity are found to depend largely upon the proper balance between the heat produced by the body within and that which is lost from the skin, any retardation of heat loss causes discomfort and depression, and finally physiological derangement As temperature rises humidity becomes of increasing importance, because the body, unable to get rid of heat fast enough by convection and radiation, has to rely more and more upon evaporation by means of the sweat glands At high temperatures, in fact, the body behaves rather like a wet-bulb thermometer and the figure registered by this type of instrument gives a fair idea of the conditions with which it has to cope The more moisture the air contains the less it can remove by evaporation from the skin, and when the wet-bulb registers more than 80° F work must cease or heat will be generated faster than it is lost When 90° F is reached on the wet-bulb the body will be unable to get rid of the heat produced in the processes needed to carry on life, and its temperature will rise until heat-stroke occurs Movement of the air, by favouring evaporation, is generally beneficial at high temperatures, but when the air is warmer than the body it becomes disadvantageous, since the air now warms by contact more than it cools by evaporation At low temperatures the wet-bulb loses its significance in favour of the dry bulb, because evaporation is not the important means by which heat is dissipated and the sweat glands are not in action

Much attention has been paid to the influence of high temperatures, and the influence of cold has also been studied, though less intensively, as it is easier by exercise or external means to maintain bodily warmth But what is specially interesting is the determination of an optimum temperature A constant environment produces, of course, a feeling of stagnation and lacks the power to stimulate It is found, however, that, on the whole, human activity, measured by industrial output, is at its best at temperatures ranging round 65° F At this figure there are fewest accidents and least sickness, metabolism is at its lowest and comfort is maximal The adverse influence of a rise of temperature is found to be greater for each degree of rise than for each degree of fall The importance of these facts in industry can hardly be exaggerated, for it is usually possible to regulate environmental heat by ventilation or refrigeration In time to come, domestic and business houses may have a cooling system for the summer, as they now have a heating system for winter

Efforts are being made to provide the hygienist with devices for estimating the efficiency of ventilation At present two are under close investigation—namely, Dr Leonard Hill's kata-thermometer, which records the cooling power of air, and an effective temperature index which comes from United States These are based on the same fundamental principles and entire agreement has not yet been reached as to which is the more useful Possibly each has advantages in its country of origin owing to differences in climatic conditions The kata-thermometer is likely to be used in this country until, if ever, an effective temperature index is worked out experimentally here

THE WILKINS COMMITTEE

THE Society of Superintendents of Tuberculosis Institutions has appointed a subcommittee to deal with the after-care of cases leaving these institutions, and also to afford opportunity for superintendents and others to acquire information about candidates suitable for posts as they fall vacant The members of the Society were, we understand, actuated by the feeling that more effort should be made to induce such institutions to employ tuberculous persons on their staff It has been found that, being conversant with the daily routine and the accepted line of treatment, they do excellent work and are in general a desirable category of servant Bringing together would-be employers and those requiring employment should therefore play a helpful part in the after-care of tuberculous patients Those who have employed such ex-patients at sanatoriums realise the feeling of relief with which they do their work, knowing they are safe and sheltered At Nayland at the present time 64 out of 150 members of the staff are ex-patients, their number makes it possible to select some of the staff from the point of view of character as well as of health—a matter of real gain Ex-patients are found suitable for all posts except the heads of departments, where work must sometimes be done under pressure unsuitable for tuberculous people The committee, which is called after the late Dr A G Wilkins who originated the idea, is making a beginning with tuberculous people, but hopes to extend its efforts later to include cripples from rheumatism and heart disease, and convalescent mental cases In the first instance the scheme is to be solely in medical hands, but later on employers of labour and other interested persons will be asked to join the committee For the present, lists of vacant posts will be prepared at intervals and circulated Dr Jane Walker is chairman of the committee, and will supply information from its temporary office at 122, Harley-street, London, W 1

THE GRACILIS MUSCLE AS SPHINCTER

WE commented last year[1] on a case in which the gracilis muscle had been used to encircle the female urethra and restore urinary control Drs L P. Player and C L Callander now report[2] a case in which they used this technique with success in a man who suffered from urinary incontinence after suprapubic prostatectomy The patient was readmitted to hospital eight months after the removal of his prostate to teach him control and to clear up a bladder infection Two surgical attempts to repair the internal sphincter resulted in sloughing of the tissues and a worse state of incontinence than before Two and a half years after his first operation he was admitted to hospital again and Deming's operation was performed. The authors describe their technique in detail The gracilis muscle was severed at the level of the internal condyle of the femur, freed up to the entry of its nerve- and blood-supply, and then tunnelled under a did of the lower ones, their calorie needs would be supplied by smaller amounts of the former, and if their consumption of food were consequently lowered their intake of wheat germ would be correspondingly reduced V E Nelson and his co-workers do not consider that the evidence for the existence of vitamin E is adequate, but J C Drummond states that work has been done in his laboratory which fully confirms Evans's work as to the existence of vitamin E E V McCollum and his co-workers not only accept the existence of vitamin E, but they also make an interesting suggestion as to its possible function They have been troubled for a considerable time by the appearance, among their experimental rats, of an ophthalmia which they feel cannot be due to any lack of vitamin A At one time they attributed the eye trouble to some error in the salt mixture and called it a salt ophthalmia In a paper published this year they correlate the ophthalmia with the death of fœtuses on a diet deficient in vitamin E, and regard both as due to an iron insufficiency They ascribe to vitamin E a function with regard to iron assimilation and state that, on the diet which they use, the ophthalmia and sterility produced by it can be cured either by adding vitamin E or by substituting ferric citrate for the ferrous sulphate previously used If these results are confirmed, vitamin E takes its place with the other vitamins as a dietary constituent, vital for growth and maintenance

[1] THE LANCET, 1926, i 873

[2] Jour Amer Med Assoc, March 26th, 1927

There is at present little evidence that lack of vitamin E is an important ætiological factor in human disease, but Prof E Poulsson, of Oslo, has published an interesting case An apparently healthy woman, after bearing a normal child followed by a weakly one, had five successive pregnancies in which the child perished just before full term For the next two pregnancies cod-liver oil was administered liberally and a healthy child resulted in each instance Whatever may be the lesson to be drawn from this case, cod-liver oil cannot be regarded as a rich source of vitamin E, but Prof Poulsson suggests its administration in cases of habitual and unexplained abortion

THE DETERMINATION OF SULPHUR DIOXIDE IN FOOD

THE Ministry of Health has decided what foods and articles used in the preparation of food may contain preservatives, and the kinds and amounts of these tolerated substances which may be allowed This in itself is a task requiring knowledge and discretion It is, however, one thing to fix a standard or limit and another to enforce it The quantities allowed are in all cases small, and it is not always easy to determine whether an excess has been added Sulphur dioxide is volatile, easily oxidised to sulphuric acid, and forms, with many substances likely to occur in foods, condensation products which are non-volatile and fairly stable The most obvious means of determination is conversion, by oxidation, into sulphate Here alternatives are possible, either the amount of oxidising agent required may be determined or the sulphate ions when formed may be either precipitated and weighed as barium sulphate or titrated acidimetrically The former process can be carried out volumetrically, the gravimetric one requires more time and skill Since, however, 1 part of SO_2 yields about 3 6 parts of $BaSO_4$ it has some advantages If it were merely a matter of determination of SO_2 in clean aqueous solutions the choice of method would be merely a matter of convenience The actual substances dealt with in an analytical laboratory do not always present the clear-cut case which is possible in an educational institution, and foods contain various interfering constituents Since almost all foods contain substances which will react with the usual oxidising agents and few are free from either sulphur compounds which will yield sulphates or from sulphates themselves, it is usually necessary to take advantage of the volatility of sulphur dioxide in order to obtain a clean, sulphate-free liquid. The ease with which sulphur dioxide forms condensation compounds renders something more than simple distillation necessary, whilst its easy oxidisability points to the need of distillation away from air

A great deal of research, not all of the most convincing kind, has been done on this matter in this country and abroad A monograph by Dr G W Monier-Williams, issued by the Ministry of Health, contains a bibliography of over 100 papers devoted to sulphur dioxide in foods The Ministry and Dr. Monier-Williams must be congratulated on having avoided the mind-destroying pitfall of standard methods There are, it must be admitted, some cases where the substance to be determined, although physically or physiologically definite, is not well characterised chemically or its characteristic forms or compounds are difficult to separate quantitatively or to deal with when separated In such cases a standard method is necessary in order that comparable results may be obtained by different workers In other cases the standard method is a sop to intellectual indolence Critical investigation of the work of others and some well thought-out experimental work has enabled Dr Monier-Williams to evolve a method of general application in which distillation with hydrochloric acid, in preference to the frequently used phosphoric acid, and oxidation of the SO_2 in the distillate with hydrogen peroxide overcomes some of the difficulties in the way of exact work The means used to verify the accuracy of the method are described Some interesting results showing the very small effect which the sulphur in gas used for heating has on liquids digested over gas flames are given It appears that those who are called upon to examine foods for this preservative may feel a reasonable certainty as to the accuracy of their work if they will pay due regard to the facts set forth in the report This is matter for congratulation, as both commerce and the public interest may suffer if new enactments are found to be applicable only on a highly speculative basis

BIRTH TRAUMA AS PROTOTYPE OF FEAR.

IN a letter which we publish in another column a San Francisco correspondent refers to the importance of the trauma of birth in the mental development of the human child The view that the physical reactions produced by the trauma of birth may stand as a prototype of the emotion of fear has been, as our correspondent points out, reached by the psycho-analytic route Erasmus Darwin expressed an almost identical view in 1794, when he wrote[1] —

> As soon as the young animal is born, the first important sensations that occur to him are occasioned by the oppression about his precordia for want of respiration, and by his sudden transition from ninety-eight degrees of heat into so cold a climate He trembles, that is, he exerts alternately all the muscles of his body, to enfranchise himself from the oppression about his bosom, and begins to breathe with frequent and short respirations, at the same time the cold contracts his red skin, gradually turning it pale, the contents of the bladder and of the bowels are evacuated and from the experience of these first disagreeable sensations the passion of fear is excited, which is no other than the expectation of disagreeable sensations This early association of motions and sensations persists throughout life, the passion of fear produces a cold and pale skin, with tremblings, quick respiration, and an evacuation of the bladder and bowels, and this constitutes the natural or universal language of this passion

If these views are valid, the bodily manifestations of fear can be regarded physiologically as conditioned allowed to stain the pillows and sheets In septic cases sleep is essential and to produce it, to stimulate the appetite and to improve the condition of the patient generally, nothing is better than open-air treatment—even in winter.

---

[1] Zoonomia, vol i, Section xvi, p 148

In toxic cases the usual methods must be adopted to get the rash out and salines may be given either rectally, subcutaneously, or intravenously, but the patient often fights against all such endeavours to assist him Stimulants such as whisky or brandy are given and hypodermic injections of camphor in oil or—better still—caffeine-sodio-salicylate. Unfortunately, the outlook in toxic cases is extremely bad Vaccines have been tried, especially for septic cases but have not proved of much use; neither have injections of polyvalent serum been very successful either in septic or toxic cases, except in a few instances where the particular serum seemed to suit the patient and given in large doses of 100 to 150 c cm. In toxic cases the administration of the whole blood of a convalescent scarlet fever patient —as recommended by Zingher—has been of great benefit but this form of treatment too, has often been disappointing It is certainly worth trying; 100 c cm at least of the donor's blood is withdrawn rapidly in sterile syringes which have been immersed in 1 per cent sodium citrate solution, and injected intramuscularly into the thigh of the patient In favourable cases there is—following the injection—a fall of temperature and pulse-rate and the patient rapidly improves

Scarlet Antitoxin Treatment.

Evidence is increasing that scarlet antitoxin when injected early enough and in sufficient dosage blanches the rash lowers the temperature and improves the general condition of the patient, so shortening the disease and lessening the likelihood of complications. The most marked benefit is seen in the restless semi-delirious patient of the toxic type—the antitoxin apparently neutralising the toxæmia. In the septic case improvement often follows the injection of the antitoxin though complications may still result—especially if the serum is not given sufficiently early. In many patients the antitoxin apparently lessens the subsequent desquamation, but in others this is not so, probably because the serum is given too late Concentrated scarlet antitoxin should be given intramuscularly in doses of 10 to 40 c cm, or more to moderately severe cases In mild cases 10 c cm is probably sufficient, but large amounts must be given in toxic cases and preferably intravenously, if possible, failing this intramuscularly into the outer aspect of the thigh. Concentrated antitoxin is better than unconcentrated serum as there will be less risk of serum reactions following in the shape of rashes which are sometimes accompanied by slight temperature, the rashes are mainly urticarial in type.

The Care of the Patient during Convalescence

Otitis media should be treated with fomentations which are soothing and often hasten discharge from the ear Paracentesis should not be delayed if it seems likely to be called for. *Otorrhœa* requires gentle douching with warm boric lotion or hydrogen peroxide —many prefer merely to mop up the discharge and consider douching or syringing dangerous A *superficial mastoid abscess* requires a simple incision right through the periosteum, but if the mastoid cells are involved a more radical operation is called for. *Rhinitis* is treated on general lines If it is due, as it often is, to a K L.B infection, 1500 units of antitoxin will dry up the rhinorrhœa. If the otorrhœa or rhinitis continue and tend to become chronic, then the removal of the tonsils and adenoids is the only thing to do and often clears up the discharges *Adenitis* is treated by fomentation and, if necessary by an incision where the abscess, which sometimes results, is ripe *Arthritis* seldom requires treatment other than warmth to the parts, unless suppuration occurs when drainage is necessary *Nephritis* is treated in the usual way by promoting diaphoresis and keeping the bowels well open with Epsom salts or jalap (dose 30–60 g) If convulsions occur, blood-letting should be performed The urine especially during the nephritic period (sixteenth to twenty-sixth day) requires to be examined daily as there is always the danger of a sudden toxic nephritis occurring. Only a trace of albumin may be found in routine examination, but the patient may die suddenly in a few hours with a high temperature Slight adenitis often precedes nephritis and vomiting is a danger-signal The majority of cases of nephritis recover if treatment is early and prompt and chronic nephritis is rare A Osman and H Carter have recently suggested the administration of alkalies as a prophylactic against this complication

The Dick Test and the Schultz-Charlton Reaction in Scarlet Fever.

The majority of patients suffering from scarlet fever give a positive Dick test if the test is performed during the height of the rash This is replaced by a negative reaction during convalescence, the antitoxin produced during the disease being apparently specific for the toxins of the *Streptococcus hæmolyticus* The serum of a convalescent or scarlet antitoxin if injected intracutaneously at the height of the rash is capable of neutralising the toxin in the skin, and blanching occurs, giving a positive Schultz-Charlton reaction If, on the other hand, an individual with a rash shows a negative Dick test and a negative Schulz-Charlton reaction then the rash is not likely to be one of scarlet fever, neither will it be due to scarlet fever if with a negative Schultz-Charlton reaction a positive Dick test is shown right from the beginning of the illness to the end of convalescence The serum of such an individual, too will not blanch a definite scarlet rash

The Dick test shows that about 60 per cent of children between 1 and 5 years, and 35 per cent between 5 and 10 years are susceptible to scarlet fever. Nurses in fever hospitals who are Dick-positive reactors should be actively immunised against scarlet fever, and the time will undoubtedly come when large numbers of children too will have to be protected Scarlet fever antitoxin can confer a passive immunity lasting only a few weeks but an active immunity lasting for 18 months to three years at least, may result from injections of increasing amounts of the toxin of the streptococcus of scarlet fever A total injection of 20 000 skin test doses is recommended, beginning with one of 250 such doses Children under 5 years of age should be immunised against both scarlet fever and diphtheria without any preliminary Dick and Schick tests but after 5 years such tests are necessary to pick out the positive reactors

The Schick Test and Diphtheria in Scarlet Fever.

If a patient during the time of the rash in scarlet fever has a faucial lesion suggestively diphtheritic and shows a positive Schick test then it is wise to administer diphtheria antitoxin If on the other hand, a negative Schick reaction occurs, the faucial lesion is almost certainly septic in nature, even though it involves the uvula. Even if diphtheria antitoxin is administered at the same time as the Schick test is performed, a negative reaction may be taken as showing that the patient is not suffering from concurrent diphtheria, and is really immune to that disease. If during the convalescence of scarlet fever a patient develops speckling or patching on the tonsils and that individual is a Schick positive reactor, then it is wise to administer a small dose of diphtheria antitoxin which can be repeated if necessary. A negative reactor with speckling or patching on the tonsils may safely be left alone. If tonsils and adenoids have to be removed for any reason during the convalescence of scarlet fever 1500 units of antitoxin should always be injected to confer a passive immunity if the individual is a positive reactor to the Schick test. On the other hand, if the patient is known to give a negative Schick reaction no diphtheria antitoxin is necessary, and anything developing later on the fauces may be regarded as merely septic.

JOHN McGARRITY, M.D. Edin, D P.H Edin & Glasg.,
Resident Medical Superintendent, Isolation Hospital, Cardiff

bridge of intact skin to the perineum It was sutured with catgut to the corpora cavernosa, the free end being rolled over the corpus cavernosum urethræ and stitched to itself The catheter and sutures were removed a week after operation and the patient then declared that he could control his bladder, and woke up to pass urine for the first time since his first operation A month later he was able to control urine while in bed but leaked a little when up and about For this reason the wound was reopened and, as anticipated, the gracilis was found to be loosely rolled round the corpus cavernosum owing to absorption of the stitches uniting it to the corpora cavernosa The loop was tightened up, after which he regained complete control in proportion to his physical energy When very tired he sometimes has to lie down to regain control In a man of 66 this result is gratifying Cystoscopy on several occasions has shown that there is no residual urine and that there is distinct voluntary contraction in the transplanted muscle So great is this power that the orderly was unable to remove a No 16 soft rubber catheter until the muscle relaxed It appears that Deming's technique will prove satisfactory for these very trying cases; if it does its inventor will have saved a great deal of distress and inconvenience to the unfortunate sufferers from otherwise incurable incontinence

---

A CONFERENCE ON GOITRE.

THE stream of published reports from many parts of the world shows that an immense number of workers are trying to throw light on the ætiology of endemic goitre, and are seeking means of preventing the disease The investigations and experiments made in Switzerland have been the starting-point of much of this research, and it is fitting that an invitation should come from that country to an international congress, where opinions may be ventilated The idea of such a conference was first put forward in 1923 by the directors of the surgical clinics of Basle and Berne, Prof G Hotz and Prof F de Quervain The project could not be realised at once, but difficulties have now been overcome, and the Swiss Goitre Commission, having sent invitations to a number of foreign authorities, has arranged for the conference to be held at Berne from August 24th to 26th of this year It will not be a general congress, but is called "a simple meeting of men of science who have made researches connected with the study of the problems of goitre" Amongst those who are to take part are Prof L Aschoff (Freiburg i/B), Prof C Wegelin (Berne), Dr David Marine (New York), Prof H S Plummer (Rochester, U S A), Prof Eiselsberg (Vienna), Prof F de Quervain (Berne), Prof L Berard (Lyons), Lieut-Colonel R McCarrison (I M S), Prof B Galli-Valerio (Lausanne), Dr E Bircher (Aarau), Prof J. Wagner-Jauregg (Vienna), Dr Muggia (Sondrio), and Prof. W Silberschmidt (Zürich) On August 27th Prof de Quervain will give a demonstration at the surgical clinic The President of the Swiss Goitre Commission is Dr H Carrière, and the congress will be held at the University of Berne

---

AFTER the death of Sir William Macewen, professor of surgery in the University of Glasgow from 1892 to 1924, a committee was formed to raise a fund to commemorate his life and work The first purpose of the fund was to present a bust to the University, a replica being given to Lady Macewen The second purpose was the establishment of a Macewen memorial lecture, and the third the foundation of a Macewen Medal in the class of surgery The busts have been presented and the first award of the medal has been made The first memorial lecture is to be delivered by Prof Harvey Cushing, C B, M D, of Harvard University, in the Zoological Lecture Theatre of the University on Tuesday, June 21st, at 3 P M The lecture will be open to past and present students of medicine and to others who may be interested Subscribers to the Foundation Fund are specially invited.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXXVIII.

THE TREATMENT OF SCARLET FEVER

WHETHER the patient is isolated in hospital or at home, the general lines of treatment are the same The room must be well ventilated with as much light as possible A warm, stuffy room is bad, and, as long as the patient is warm in bed, conditions approaching open-air treatment are best—especially in septic cases Daily tepid sponging with soap and water is necessary while the patient is in bed During convalescence warm baths may be taken The bowels must be attended to; an enema the first day or so, as long as there is a temperature, and then simple aperients. At the time of the rash the patient must be comfortably warm in bed—preferably among blankets—and should have a soft woollen garment next the skin A couple of hot-water bottles are usually sufficient, but more may be necessary if the rash is not coming out well and is poor in colour. If this is not sufficient hot packs or mustard packs may be given to bring the rash out and a little ice to the head if the temperature rises above 104° F Whisky is useful in sharp cases as a stimulant, or brandy if the patient is sick Sleep is important, and this may be induced by tepid sponging and warm drinks such as toddy If this is not enough a little bromide or paraldehyde may be given The paraldehyde is best given by the rectum Morphia may be needed if the patient is very restless, but it is not always well borne At the end of three weeks the patient is allowed to sit up wrapped in blankets for a few days before being dressed. The risk of the individual catching cold must not be forgotten Drugs play a small part in the treatment of scarlet fever Diaphoretics are really unnecessary and the Milne treatment has now been given up

Diet

Milk is sufficient at first After the temperature falls give porridge, milk puddings, &c, and later fish; after about three weeks increase to an ordinary diet In septic cases the diet must be such as to maintain the strength of the patient In nephritis it is best to restrict the diet to milk or arrowroot &c, with occasionally some stewed fruit and cream Fluids should be given freely in all cases of scarlet fever

The Care of the Mouth, Nose, and Throat

In ordinary simple cases of scarlet fever in an adult a mild antiseptic gargle is sufficient A teaspoonful of liq thymol co in a glass of warm water is a pleasant mouth-wash and gargle The child requires a little more care, as it is unable to attend to the toilet of the mouth itself The throat may be left alone, but the tongue and mucous membranes should be thoroughly cleansed with swabs of cotton-wool dipped in a mild antiseptic solution such as thymol solution, using a swab-holder or the index-finger sheathed in a thin layer of cotton-wool The mucous membranes may then be swabbed over again in the same way with a solution of boroglycerine Finally, the tongue and lips are anointed with a mixture of boric ointment and vaseline flavoured with peppermint to keep them moist and soft Ill patients, whether adults or children, should have the toilet of the mouth thus attended to after feeds.

Septic and Toxic Cases

If the case is a septic one, with profuse nasal discharge and patching on the tonsils, the nose and throat may be gently irrigated or sprayed with mild lotions such as boric lotion, eusol, thymol, or normal saline Actual swabbing of the fauces is sometimes necessary, but in a restless patient this form of local treatment is probably unwise The discharge from the nose should be mopped up and not

I should thereby obtain the real ascending force of the sap in that stem, which succeeded according to my expectation and hence it is, that I have been insensibly led on to make farther and farther researches by variety of experiments "

Applying this method, he found the sap pressure in the vine in the bleeding season to be "five times greater than the force of the blood in the great crural artery of a horse, seven times greater than the force of the blood in the like artery of a dog, and eight times greater than the blood's force in the same artery of a fallow doe "

THE REVD STEPHEN HALES, D D,

Clark of the Closet to Her Royal Highness the Princess Dowager of Wales —F R S and Member of the Academies of Sciences at Paris and Bologna Aged 82

(From the mezzotint by McArdell after the portrait by Thomas Hudson in the National Portrait Gallery)

In the field of physiological botany Hales was certainly a pioneer, as he made the first proper scientific investigation of the flow of sap in plants and trees As in the case of his work on the circulation, this study was not only qualitative but also quantitative He measured the rate of transpiration of water from unit surface area of leaves, the rate of absorption of water by unit area of root surface, and calculated the rate of flow of sap along the stem and branches He compared the "perspiration rate" per unit area of surface of the sunflower with that of man He measured the sap pressure in stems with, and in stems without, their leaves and branches Finding that the sap pressure was upwards under all circumstances, he argued against the current theory of a circulation of the sap, and attributed its elevation to transpiration by the leaves, aided at certain seasons by a force exerted by the roots Of this work he wrote, "I have been careful in making, and faithful in relating, the results of these experiments, and wish I could be as happy in drawing the proper inferences from them" But his theory is now regarded as correct in its main essentials

Hales also invented the present-day method of studying the growth of plants, that of marking stems and leaves at equal intervals These experiments of his are of particular interest as they led him to perform a fundamental experiment on the growth of the bone "The wetter the season," he wrote, "the longer and larger shoots do vegetables usually make, because their soft ductile parts do then continue longer in a moist tender state but in a dry season the fibres soon harden, and stop the further growth of the shoot " Then surely a triumph of reasoning in comparative physiology, as the truth of his prediction was established by his subsequent experiment, which was as follows —

"As in vegetables, so doubtless in animals, the tender ductile bones of young animals are gradually increased in every part that is not hardened and ossified, but since it was inconsistent with the motions of the joints to have the ends of the bones soft and ductile, as in vegetables, therefore nature makes a wonderful provision for this at the glutinous serrated joining of the heads to the shanks of the bones, which jointing, while it continues ductile, the animal grows, but when it ossifies, then the animal can no longer grow as I was assured by the following experiment—viz, I took a half-grown *chick*, whose leg-bone was then two inches long, with a sharp-pointed iron, at half an inch distance, I pierced two small holes through the middle of the scaly covering of the leg and shin-bone, two months after I killed the *chick*, and upon laying the bone bare, I found on it obscure remains of the two marks I had made at the same distance of half an inch so that that part of the bone had not at all distended lengthwise, since the time that I had marked it, notwithstanding the bone was in that time grown an inch more in length, which growth was *mostly at the upper end of the bone, where a* wonderful provision is made for its growth at the joining of its head to the shank, called by anatomists *symphysis* "

This experiment, usually attributed to John Hunter born in 1728, was actually performed by Hales some years before that date His researches were soon to receive the recognition they deserved In 1718 he was elected a Fellow of the Royal Society on the same day as the friend and companion of his Cambridge days, William Stukely

His Religion

It may seem remarkable that scientific work like this should have been performed by a country parson

Special Articles.

STEPHEN HALES, D.D., F.R.S.,

PHYSIOLOGIST AND BOTANIST, 1677–1761

A Dissertation delivered at Corpus Christi College, Cambridge, on June 16th, 1927,

BY A. E. CLARK-KENNEDY, M.D., M.R.C.P.,
FELLOW OF THE COLLEGE; ASSISTANT DIRECTOR OF THE MEDICAL UNIT, THE LONDON HOSPITAL

Stephen Hales, a grandson of Sir Robert Hales was born at Bekesbourne in Kent on Sept. 17th, 1677. Sir Robert's eldest son, Thomas, had married Mary, heiress of Richard Wood, of Abbots Langley in Hertfordshire; Stephen was their sixth son. Having been properly instructed in "grammar learning," he was sent up to Cambridge and admitted a pensioner of this College in 1696. Intended for the Church, he studied divinity. Taking the degree of Master of Arts in 1703, he was ordained and elected a Fellow of the College in the same year. Just after Hales had been elected to his Fellowship, William Stukely came, as a scholar, to Bene't College. Stukely, an enthusiastic naturalist, made physic his principal study, to become a Fellow of the College of Physicians and well known as an antiquary in after life. With this undergraduate, some years his junior, Hales formed an intimate friendship. Together they rambled over "Gog-Magog hills and Cherry-Hunt-Moor," collecting "simples," hunting for fossils in the chalk pits, and catching butterflies, "having contrived an instrument for taking them." Together they studied anatomy, dissecting dogs and other animals. They also attended the public lectures that Vigani, first professor of chemistry, gave in the "Cloysters" at Queen's College, and went to see "chymical" experiments he performed in the room over the gateway at Trinity, which had been the laboratory of Sir Isaac Newton. Hales also applied himself to astronomy, and having acquired a "perfect knowledge of the Newtonian system," invented a mechanical model to demonstrate the movements of the planets.

In 1709 Hales was appointed Minister of Teddington in the county of Middlesex. Soon after he commenced a long series of researches on the physiology of plants and animals. By nature Hales was always a biologist, but at Cambridge he had been well grounded in the Newtonian physics and astronomy of his day. There, too, to good purpose, he had attended Vigani's lectures, and repeated many of Robert Boyle's experiments, learning the value of the experimental method. "Though we can never hope to attain," he wrote, "to the complete knowledge of the texture, or constituent frame and nature of bodies, yet may we reasonably expect by this method of experiments, to make farther and farther advances abundantly sufficient to reward our pains. And though this method be tedious, yet our abilities can proceed no faster; for as the learned author of the 'Procedure of Human Understanding' observes:—

> 'All the real true knowledge we have of nature is intirely experimental, insomuch that, how strange soever the assertion seems, we may lay this down as the first fundamental unerring rule in physics, *That it is not within the compass of human understanding to assign a purely speculative reason for any one phenomenon in nature.*'

So that in natural philosophy we cannot depend on any mere speculations of the mind; we can only with the mathematicians, reason with any tolerable certainty from proper data, such as arise from the united testimony of many good and credible experiments."

Hales therefore applied the experimental method, and quantitative methods in particular, to the study of biology, as rigidly as Newton, Boyle, and others had used it in the elucidation of the laws of physics and chemistry. Harvey had inferred the circulation of the blood from anatomical observation and then confirmed it by experiments on living animals. Hales proceeded differently. From the start he applied his knowledge of physics and mechanics to the problems of physiology. Thus, not only did he become a great experimental biologist, but one of the outstanding figures in the foundation of the mechanistic physiology of to-day.

His Work on the Circulation.

To Hales, primarily a biologist, but trained as a physicist, the circulation of the blood, discovered rather less than a century before him, must have presented a fascinating study. It is therefore not surprising that his first scientific endeavour was to make a complete quantitative investigation of the dynamics of the circulation. "Since we are assured," he wrote, "that the animal fluids move by *hydraulic* and *hydrostatical* laws, the likeliest way therefore to succeed in our inquiries into the nature of their motions, is by adapting our experiments to those laws." He therefore devised his "hæmastatical" method, which consisted of the application of the principle of the manometer to animal physiology, and performed a vast number of vivisection experiments of great technical difficulty, not in a well-equipped laboratory, but in the parsonage at Teddington in pre-anæsthetic days! By tying tubes into the arteries and veins of living animals he was the first man to record the blood pressure. In so doing, not only did he advance our knowledge of cardiovascular physiology by a definite and important step, but at the same time laid the foundation of an important clinical method in the study and diagnosis of disease. For this performance Hales is justly famous. But, in addition, he investigated almost all the mechanical aspects of the circulation, and made a more complete study of cardio-dynamics than even Lower had done before him. His description of this branch of physiology is so complete and quantitative, so essentially modern in all its tendencies that it reads like a chapter in a present-day text-book. By recording the pulse-rate during life, and then injecting the heart with wax, he computed the circulation rate in horses, cattle, deer, and dogs. He showed that in large animals the blood flow is relatively less than in small, but, in the absence of a true conception of respiration and metabolism, he failed to realise the significance of this result. He estimated the actual velocity of the blood stream in the different arteries and veins. He measured the velocity of the blood in the tissue capillaries by observation with a microscope, and compared it with indirect calculations of the velocity of the blood in those of the lungs. Studying blood flow in the tissues, he estimated the capillary blood pressure, and demonstrated vaso-constriction by cold, vaso-dilatation by heat. Lastly, by pointing out that the heart responds to increased venous return by increased systolic output, he laid the foundation of the conception now known as "Starling's Law."

His Work on the Physiology of Plants.

Hales was essentially a comparative physiologist. He alternated between experiments on plants and experiments on animals. Observations on the physiology of plants suggested corresponding experiments on animals. Observations on animals suggested corresponding experiments on the physiology of plants.

> "About twenty years since," he writes, "I made several hæmastatical experiments on dogs, in order to find out the real force of the blood in the arteries; at which times I wished I could have made the like experiments to discover the force of the sap in vegetables; but dispaired of ever effecting it, till by mere accident I hit upon it, while I was endeavouring to stop the bleeding *of an old stem of a vine,* which was cut too near the bleeding *season,* which I feared might kill it. Having tied a piece of bladder over the transverse cut of the stem, I found the force of *the sap did* greatly distend the bladder; whence I concluded, that if a long glass tube were fixed there in *the same manner,* as I had before done to the arteries *of several living* animals

clusion that "air" enters into the constitution of plants, and that an important function of the leaves was absorption of this form of nourishment "It is by this amphibious property of air," he wrote, "that the main and principal operations of nature are carried on", and then this significant sentence "May not light also, by freely entering the expanded surfaces of leaves and flowers, contribute much to the ennobling the principles of vegetables?" As Michael Foster pointed out, Hales was the first man to give a clear enunciation of the existence of gases in both a combined and a free state

True to his comparative physiology again, from absorption of air by plants he turned his attention to respiration in man After performing a number of experiments on combustion without much success, he repeated Mayow's experiment on the respiration of animals Mayow had shown that animals absorb a part of the air they breathe, but Hales carried things a step further, when he came to the conclusion that respiration in some way modifies the properties of the air left over so as to make it unfit for life and for combustion Thus he was led to experiment on himself, and to perform the first re-breathing experiment Taking a well-softened bladder, and closing his nostrils, he proceeded to breathe in and out of it "In less than half a minute," he wrote, "I found a considerable difficulty in breathing, and was forced after that to fetch my breath very fast, and at the end of the minute, the suffocating uneasiness was so great, that I was forced to take away the bladder from my mouth" Then, in an attempt to find "some means to qualify and rebate the deadly noxious quality of these (expired) vapours," he constructed a more complicated form of re-breathing apparatus with inspiratory and expiratory valves, so arranged that his expired air had to pass through diaphragms of cloth before being inspired again. He could re-breathe the air contained in this apparatus for one and a half minutes only when there were no diaphragms When, however, these were moistened with a solution of "sal tartar," and then replaced, re-breathing could be continued for five to eight minutes Moreover, the diaphragms increased in weight to a greater extent than he could account for by absorption of water only! If Mayow can be said to have discovered oxygen, surely Hales described carbon dioxide! Throughout Hales's writings there is no mention of the phlogiston theory By this silent refusal to follow Stahl, he kept alive the spark of truth that Mayow had lit, to be rekindled more than a century later by Black, Priestly, and Lavoisier It is almost impossible to conceive of the perspective of Hales's outlook on these problems But if only he had followed Mayow a little more literally, and conceived, as he had, of different kinds of gases, instead of one "air" with variable properties, he might well have arrived at a true conception of respiration Be this as it may, Hales's researches had a great practical outcome in his work on ventilation

Prince Frederick of Wales was in the habit of paying him visits in his laboratory at Teddington to see these curious experiments in which he was almost constantly engaged The Princess of Wales, mother of George III, also had considerable regard for him, and through her influence he was appointed a Canon of Windsor by the King

> "But declining to accept it, he immediately waited upon his Royal Patroness, and prevailed upon her to waive the honour so kindly intended for him, preferring his retirement at Teddington to any other situation, as being more favourable to his philosophical persuits His circumstances, he said, were such as entirely satisfied his desires, and an ampler income would only be a greater encumbrance"

Later, however, he accepted the appointments of Clark of the Closet to the Princess Dowager, and Chaplain to the young Prince, her son

His Temperance Campaign

In the early part of the eighteenth century the introduction of gin had given a new impetus to drunkenness In the streets of London gin-shops invited passers-by to get drunk for a penny, dead drunk for twopence Hales was not a "teetotaler" in the modern sense, indeed, he advocated the drinking of wine But against this growing social evil he launched a vigorous campaign, when in 1734 he published an anonymous pamphlet entitled "A Friendly Admonition to the Drinkers of Brandy and other Distilled Spirituous Liquors" Two years later he was associated with a number of physicians in a tract entitled "Distilled Spirituous Liquors, the Bane of the Nation," a tract to which Fielding referred, when, in 1751, as a Bow-street magistrate, he urged the legislature to enact some measure of prohibition A month later Hogarth published his print, "Gin Lane," designedly produced at so low a price as to be within the means of all Forced into action, Parliament passed a Bill "For Restricting the Sale of Spirituous Liquors," and some of its provisions are in force to this day This temperance campaign afforded him considerable satisfaction in the closing years of his life To the Rev William Henry he wrote as follows.—

> "Tho' I thank God, that I have been blessed with Success in promoting several Things which will be of a lasting Benefit to Mankind, yet nothing I have done, has given me near the Satisfaction, that the public Testimony, which I have for 26 Years past borne against these infernal Spirits, ten different Times, has given me And as I intend soon to begin to print my second Volume on Ventilators, I have in the strongest Terms expostulated on the Subject, hoping that as Ventilators are coming into more and general Use, so my Book on that Subject will probably be proportionately dispersed about the World, In which I have given my last dying Testimony against them, I being this Day, I bless God, *Eighty years* old"

Mrs Stephens's Medicines

In contrast to his exact science we now turn to an amazing episode in his career A certain Mrs Joanna Stephens, daughter of a gentleman of good estate and family in Berkshire, accidentally discovered a method of dissolving the stone Many persons afflicted with the distemper of the stone received considerable relief from Mrs Stephens's medicines, and among them a no lesser personage than the Postmaster-General In the year 1737 the cures performed by her medicines were so numerous and so well attested that the speedy publication of them was deemed to be of great importance to mankind. Accordingly, after an attempt to raise the money by public subscription had failed, Mrs Stephens was advised to apply to the House of Commons for a reward when she should declare the secret of her medicines The necessary Bill was brought in, passed both Houses and received the Royal Assent on June 14th, 1739 By this Bill it was enacted that the sum of £5000 should be applied and paid to the said Joanna Stephens when she had divulged the nature of her medicines and her methods of preparing the same, and when the trustees appointed under the Act had satisfied themselves of the utility, efficacy, and dissolving power thereof The 30 trustees included the Archbishop of Canterbury, the Lord Chancellor, the Lord President of the Council, the Lord Privy Seal, the Lord Chamberlain, the Bishops of Oxford and Gloucester, the Speaker of the House of Commons, a number of noblemen, gentry, physicians, and surgeons, and the Rev Stephen Hales Mrs Stephens at once divulged the secret of her medicines to the Archbishop These consisted of egg-shells, snails, and swines-cresses, burned to a blackness until the snails had done smoking, herbs, soaps, and honey! On March 5th the trustees met in the House of Lords Four persons appeared before them who had taken Mrs Stephens's medicines The physicians and surgeons testified with one accord to the completeness with which the distemper of the stone had been eradicated The trustees signed the necessary certificate required by Act of Parliament and Mrs Stephens duly received her reward of £5000 at the Exchequer And what part did Hales play in this remarkable affair? He had already made numerous

But in the study of pure science, though he sought for mechanical explanations always, Hales found confirmation of his faith No inkling of any conception of evolution ever crossed his mind The world had been created by God just as Hales found it

> "Nature works according to the laws established at her first institution," he wrote "The study of nature will ever yield us fresh matter of entertainment, and we have great reason to bless God for the faculties and abilities he has given us, and the strong desire he has implanted in our minds, to search into and contemplate his works, in which the farther we go, the more we see the signatures of his wisdom and power, everything pleases and instructs us, because in everything we see a wise design The further researches we make into this admirable scene of things, the more beauty and harmony we see in them and the stronger and clearer convictions they give us, of the being, power and wisdom of the divine Architect, who has made all things to concur with a wonderful conformity, in carrying on, by various and innumerable combinations of matter, such a circulation of causes and effects, as was necessary to the great ends of nature "

Hales was an ardent parish priest, he served his parish with the same energy and zeal as he prosecuted his scientific experiments He made the women of his parish do public penance for irregular behaviour He prevailed upon the Lord of the Manor to enlarge the churchyard He arranged for a new parish water-supply He caused a lantern to be erected on the church tower

> "in which to hang a loud bell to be heard at a much greater distance, not only for the benefit of the serious and the well disposed, but also as a constant memento to the careless, the negligent, and the profane, who with the wicked in Job are but too apt to say *Who is the Almighty that we should serve him? And what profit should we have if we should pray unto him?*"

On this bell Hales ordered the words "Worship God" to be inscribed His church was soon too small to accommodate all those who would come to hear him preach He therefore built a new aisle, and replaced the old wooden tower by a brick one The money for these alterations was largely raised by the sale of pews, which were leased to their prospective owners, their heirs and assignees for ever, and all for the sum of 4*s* 3*d* the square foot! But, in addition, Hales contributed £200 himself This information is gleaned from the Teddington parish registers in which he also made the following quaint entries "John Rolt, who was murdered in fighting for the maypole, buried May 23rd, 1710 James Parsons, who had oft eat a shoulder of mutton and a peck of hasty pudding at a time which caused his death, buried March 27th, 1744, aged 35" Here too is recorded the one tragedy of his life In 1720 he had married Mary, daughter of Dr Richard Newce, of Much Hadham, Hertfordshire But his wife died without issue just a year later, and in the register he had to write, "Mary Hales, my dear wife, was buried Oct 10th, 1721"

His Character

Of his character let one of his contemporaries speak "He possessed a native innocence and simplicity of manners, which the characters of other men, and the customs of the world could never alter, and though he often met with many unworthy objects of this kind and uncharitable offices, yet they never once lessened his natural and unwearied disposition of doing good and relieving distress His temper, as well as the powers of his understanding, were happily fitted for the improvement of natural philosophy, possessing, as he did, in an uncommon degree, that *industry and patient thinking*, which Sir Isaac Newton used modestly to declare, was his own only secret by which he was enabled so fortunately to trace his wonderful analysis of nature Dr Hales began his inquiries into natural knowledge very early in life, and he continued them uniformly as his darling amusement, being engaged in experiments until a few weeks of his death His industry had likewise this farther excellence, that it was always pointed at the general good of his fellow creatures, agreeable to the unlimited benevolence of his heart, and being animated with the success of some of his more useful discoveries, his knowledge appeared to everybody near him to feed his mind with a nourishment that gave him, in decline of life, and even in its last stages, that vigour and serenity of understanding, and clearness of ideas, which so few possess, even in the flower of manhood and which he used often to say, he valued as the most perfect of all human pleasures There are two things in his character which particularly distinguish him from almost every other man the first was, that his mind was so habitually bent on acquiring knowledge, that, having what he thought an abundant income, he was solicitous to avoid any farther preferment in the church, lest his time and his attention might thereby be diverted from his other favourite and useful occupations The other feature of his character was no less singular he could look even upon wicked men, and those who did him unkind offices, without any emotion of particular indignation, not from want of discernment or sensibility, but he used to consider them only like those experiments, which, upon trial, he found could never be applied to any useful purpose, and which he therefore calmly and dispassionately laid aside"

His Work on the Chemistry of Respiration

But to return to his science An accidental observation, that bubbles of air ascended with the sap, was responsible for Hales leaving the comparatively simple problem of the circulation of the blood, to attack a much more difficult subject—the chemistry of respiration Any account of his work in this field would be meaningless without some statement of the position of knowledge of this subject in his day Galileo and Newton had already made physics an exact science But chemistry, a long way behind, remained an empirical and largely speculative study The conception of chemical elements had not yet been formed, a logical formulation of chemical compounds was not yet possible Chemical substances were still described and classified according to their properties In 1660 Robert Boyle had demonstrated that a candle became extinguished, and that an animal died when placed in an evacuated vessel Nine years later Lower discovered that blood takes up air At about the same time Mayow, of All Souls, but for whose untimely death the history of science might read very differently, came to the conclusion that it was not the whole air, but a part of it only, which was essential for respiration and combustion alike, this fraction he called the "spiritus nitro æreus" Thus Mayow virtually discovered oxygen, and laid the foundation of a true conception of animal heat, when he supposed that this arose from the combination of his nitro-aereal spirits with the sulphurous particles of the blood Mayow clearly realised that a part of the air went into combination with the blood, but he failed to realise that anything came out. His work, however, received but scant attention, and 30 years later knowledge was put back over a century, when Stahl, failing to make the necessary distinction between matter and energy, introduced his phlogiston theory According to this conception, which dominated biology and chemistry for over a hundred years, when a substance burned, phlogiston departed from it, the body suffered a loss, it became dephlogisticated Stahl, rejecting the idea that animal heat was due to chemical action, returned to the old view that it arose from friction of the blood in the vessels, while his pupil Haller, writing only a few years before Hales died, denied that air entered into combination with the blood, so completely had the work of Mayow and Lower been neglected Not till 1754 did Black deal his death-blow to the phlogiston theory when he prepared carbon dioxide, and not till 20 years after Hales's death, in his eighty-fourth year, did Lavoisier enunciate the true principles of respiration, combustion, and animal heat

Applying his "statical method," Hales demonstrated that plants absorb considerable quantities of "air" By distilling vegetable substances he showed that plants contained "air" He came to the conclusion that "air" enters into the constitution of plants, and that an important function of the leaves was absorption of this form of nourishment "It is by this amphibious property of air," he wrote, "that the main and principal operations of nature are carried on", and then this significant sentence. "May not light also, by freely entering the expanded surfaces of leaves and flowers, contribute much to the ennobling the principles of vegetables?" As Michael Foster pointed out, Hales was the first man to give a clear enunciation of the existence of gases in both a combined and a free state

True to his comparative physiology again, from absorption of air by plants he turned his attention to respiration in man After performing a number of experiments on combustion without much success, he repeated Mayow's experiment on the respiration of animals Mayow had shown that animals absorb a part of the air they breathe, but Hales carried things a step further, when he came to the conclusion that respiration in some way modifies the properties of the air left over so as to make it unfit for life and for combustion Thus he was led to experiment on himself, and to perform the first re-breathing experiment Taking a well-softened bladder, and closing his nostrils, he proceeded to breathe in and out of it "In less than half a minute," he wrote, "I found a considerable difficulty in breathing, and was forced after that to fetch my breath very fast, and at the end of the minute, the suffocating uneasiness was so great, that I was forced to take away the bladder from my mouth" Then, in an attempt to find "some means to qualify and rebate the deadly noxious quality of these (expired) vapours," he constructed a more complicated form of re-breathing apparatus with inspiratory and expiratory valves, so arranged that his expired air had to pass through diaphragms of cloth before being inspired again. He could re-breathe the air contained in this apparatus for one and a half minutes only when there were no diaphragms When, however, these were moistened with a solution of "sal tartar," and then replaced, re breathing could be continued for five to eight minutes Moreover, the diaphragms increased in weight to a greater extent than he could account for by absorption of water only! If Mayow can be said to have discovered oxygen, surely Hales described carbon dioxide! Throughout Hales's writings there is no mention of the phlogiston theory. By this silent refusal to follow Stahl, he kept alive the spark of truth that Mayow had lit, to be rekindled more than a century later by Black, Priestly, and Lavoisier It is almost impossible to conceive of the perspective of Hales's outlook on these problems But if only he had followed Mayow a little more literally, and conceived, as he had, of different kinds of gases, instead of one "air" with variable properties, he might well have arrived at a true conception of respiration Be this as it may, Hales's researches had a great practical outcome in his work on ventilation

Prince Frederick of Wales was in the habit of paying him visits in his laboratory at Teddington to see these curious experiments in which he was almost constantly engaged The Princess of Wales, mother of George III, also had considerable regard for him, and through her influence he was appointed a Canon of Windsor by the King

"But declining to accept it, he immediately waited upon his Royal Patroness, and prevailed upon her to waive the honour so kindly intended for him, preferring his retirement at Teddington to any other situation, as being more favourable to his philosophical persuits His circumstances, he said, were such as entirely satisfied his desires, and an ampler income would only be a greater encumbrance"

Later, however, he accepted the appointments of Clark of the Closet to the Princess Dowager, and Chaplain to the young Prince, her son

His Temperance Campaign

In the early part of the eighteenth century the introduction of gin had given a new impetus to drunkenness In the streets of London gin-shops invited passers-by to get drunk for a penny, dead drunk for twopence Hales was not a "teetotaler" in the modern sense, indeed, he advocated the drinking of wine But against this growing social evil he launched a vigorous campaign, when in 1734 he published an anonymous pamphlet entitled "A Friendly Admonition to the Drinkers of Brandy and other Distilled Spirituous Liquors" Two years later he was associated with a number of physicians in a tract entitled "Distilled Spirituous Liquors, the Bane of the Nation," a tract to which Fielding referred, when, in 1751, as a Bow-street magistrate, he urged the legislature to enact some measure of prohibition A month later Hogarth published his print, "Gin Lane," designedly produced at so low a price as to be within the means of all Forced into action, Parliament passed a Bill "For Restricting the Sale of Spirituous Liquors," and some of its provisions are in force to this day This temperance campaign afforded him considerable satisfaction in the closing years of his life To the Rev William Henry he wrote as follows —

"Tho' I thank God, that I have been blessed with Success in promoting several Things which will be of a lasting Benefit to Mankind, yet nothing I have done, has given me near the Satisfaction, that the public Testimony, which I have for 26 Years past borne against these infernal Spirits, *ten different Times, has given me And as I intend soon to* begin to print my second Volume on Ventilators, I have in the strongest Terms expostulated on the Subject, hoping that as Ventilators are coming into more and general Use, so my Book on that Subject will probably be proportionately dispersed about the World, In which I have given my last dying Testimony against them, I being this Day, I bless God, *Eighty years* old"

Mrs Stephens's Medicines

In contrast to his exact science we now turn to an amazing episode in his career. A certain Mrs Joanna Stephens, daughter of a gentleman of good estate and family in Berkshire, accidentally discovered a method of dissolving the stone Many persons afflicted with the distemper of the stone received considerable relief from Mrs Stephens's medicines, and among them a no lesser personage than the Postmaster-General In the year 1737 the cures performed by her medicines were so numerous and so well attested that the speedy publication of them was deemed to be of great importance to mankind Accordingly, after an attempt to raise the money by public subscription had failed, Mrs Stephens was advised to apply to the House of Commons for a reward when she should declare the secret of her medicines The necessary Bill was brought in, passed both Houses and received the Royal Assent on June 14th, 1739 By this Bill it was enacted that the sum of £5000 should be applied and paid to the said Joanna Stephens when she had divulged the nature of her medicines and her methods of preparing the same, and when the trustees appointed under the Act had satisfied themselves of the utility, efficacy, and dissolving power thereof The 30 trustees included the Archbishop of Canterbury, the Lord Chancellor, the Lord President of the Council, the Lord Privy Seal, the Lord Chamberlain, the Bishops of Oxford and Gloucester, the Speaker of the House of Commons, a number of noblemen, gentry, physicians, and surgeons, and the Rev Stephen Hales Mrs Stephens at once divulged the secret of her medicines to the Archbishop These consisted of egg-shells, snails, and swines-cresses, burned to a blackness until the snails had done smoking, herbs, soaps, and honey! On March 5th the trustees met in the House of Lords Four persons appeared before them who had taken Mrs Stephens's medicines The physicians and surgeons testified with one accord to the completeness with which the distemper of the stone had been eradicated The trustees signed the necessary certificate required by Act of Parliament, and Mrs Stephens duly received her reward of £5000 at the Exchequer And what part did Hales play in this remarkable affair? He had already made numerous

But in the study of pure science, though he sought for mechanical explanations always, Hales found confirmation of his faith No inkling of any conception of evolution ever crossed his mind The world had been created by God just as Hales found it

> "Nature works according to the laws established at her first institution," he wrote "The study of nature will ever yield us fresh matter of entertainment, and we have great reason to bless God for the faculties and abilities he has given us, and the strong desire he has implanted in our minds, to search into and contemplate his works, in which the farther we go, the more we see the signatures of his wisdom and power, everything pleases and instructs us, because in everything we see a wise design The further researches we make into this admirable scene of things, the more beauty and harmony we see in them and the stronger and clearer convictions they give us, of the being, power and wisdom of the divine Architect, who has made all things to concur with a wonderful conformity, in carrying on, by various and innumerable combinations of matter, such a circulation of causes and effects, as was necessary to the great ends of nature"

Hales was an ardent parish priest, he served his parish with the same energy and zeal as he prosecuted his scientific experiments He made the women of his parish do public penance for irregular behaviour He prevailed upon the Lord of the Manor to enlarge the churchyard He arranged for a new parish water-supply He caused a lantern to be erected on the church tower

> "in which to hang a loud bell to be heard at a much greater distance, not only for the benefit of the serious and the well disposed, but also as a constant memento to the careless, the negligent, and the profane, who with the wicked in Job are but too apt to say *Who is the Almighty that we should serve him? And what profit should we have if we should pray unto him?*"

On this bell Hales ordered the words "Worship God" to be inscribed His church was soon too small to accommodate all those who would come to hear him preach He therefore built a new aisle, and replaced the old wooden tower by a brick one The money for these alterations was largely raised by the sale of pews, which were leased to their prospective owners, their heirs and assignees for ever, and all for the sum of 4*s* 3*d* the square foot! But, in addition, Hales contributed £200 himself This information is gleaned from the Teddington parish registers in which he also made the following quaint entries "John Rolt, who was murdered in fighting for the maypole, buried May 23rd, 1710 James Parsons, who had oft eat a shoulder of mutton and a peck of hasty pudding at a time which caused his death, buried March 27th, 1744, aged 35" Here too is recorded the one tragedy of his life In 1720 he had married Mary, daughter of Dr Richard Newce, of Much Hadham, Hertfordshire But his wife died without issue just a year later, and in the register he had to write, "Mary Hales, my dear wife, was buried Oct 10th, 1721"

His Character

Of his character let one of his contemporaries speak "He possessed a native innocence and simplicity of manners, which the characters of other men, and the customs of the world could never alter, and though he often met with many unworthy objects of this kind and uncharitable offices, yet they never once lessened his natural and unwearied disposition of doing good and relieving distress His temper, as well as the powers of his understanding, were happily fitted for the improvement of natural philosophy, possessing, as he did, in an uncommon degree, that *industry and patient thinking*, which Sir Isaac Newton used modestly to declare, was his own only secret by which he was enabled so fortunately to trace his wonderful analysis of nature Dr Hales began his inquiries into natural knowledge very early in life, and he continued them uniformly as his darling amusement, being engaged in experiments until a few weeks of his death His industry had likewise this farther excellence, that it was always pointed at the general good of his fellow creatures, agreeable to the unlimited benevolence of his heart, and being animated with the success of some of his more useful discoveries, his knowledge appeared to everybody near him to feed his mind with a nourishment that gave him, in decline of life, and even in its last stages, that vigour and serenity of understanding, and clearness of ideas, which so few possess, even in the flower of manhood: and which he used often to say, he valued as the most perfect of all human pleasures There are two things in his character which particularly distinguish him from almost every other man the first was, that his mind was so habitually bent on acquiring knowledge, that, having what he thought an abundant income, he was solicitous to avoid any farther preferment in the church, lest his time and his attention might thereby be diverted from his other favourite and useful occupations The other feature of his character was no less singular he could look even upon wicked men, and those who did him unkind offices, without any emotion of particular indignation, not from want of discernment or sensibility, but he used to consider them only like those experiments, which, upon trial, he found could never be applied to any useful purpose, and which he therefore calmly and dispassionately laid aside"

His Work on the Chemistry of Respiration

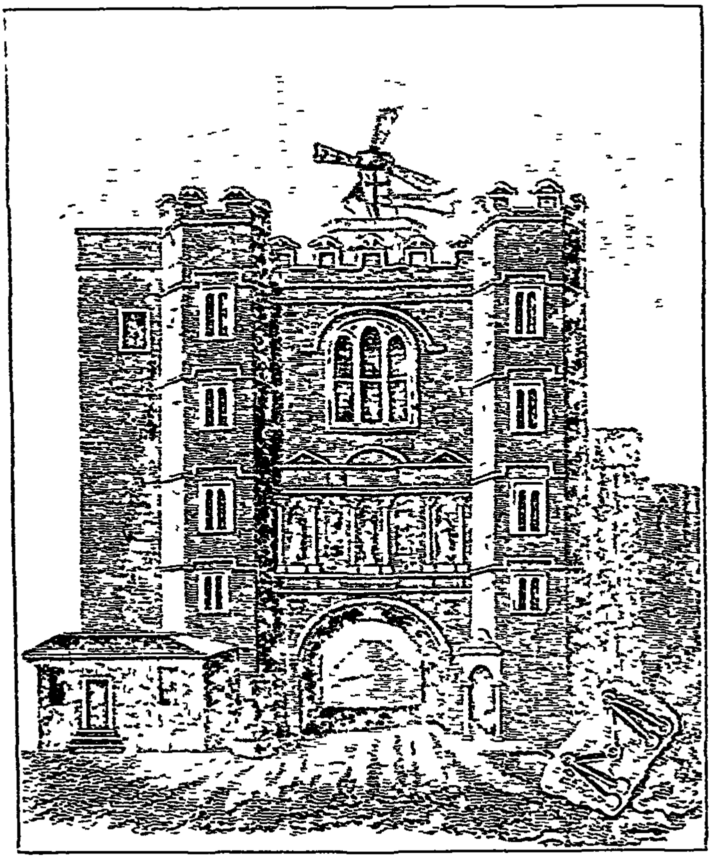
But to return to his science An accidental observation, that bubbles of air ascended with the sap, was responsible for Hales leaving the comparatively simple problem of the circulation of the blood, to attack a much more difficult subject—the chemistry of respiration Any account of his work in this field would be meaningless without some statement of the position of knowledge of this subject in his day Galileo and Newton had already made physics an exact science But chemistry, a long way behind, remained an empirical and largely speculative study The conception of chemical elements had not yet been formed, a logical formulation of chemical compounds was not yet possible Chemical substances were still described and classified according to their properties In 1660 Robert Boyle had demonstrated that a candle became extinguished, and that an animal died when placed in an evacuated vessel Nine years later Lower discovered that blood takes up air At about the same time Mayow, of All Souls, but for whose untimely death the history of science might read very differently, came to the conclusion that it was not the whole air, but a part of it only, which was essential for respiration and combustion alike, this fraction he called the "spiritus nitro æreus" Thus Mayow virtually discovered oxygen and laid the foundation of a true conception of animal heat, when he supposed that this arose from the combination of his nitro-æreal spirits with the sulphurous particles of the blood Mayow clearly realised that a part of the air went into combination with the blood, but he failed to realise that anything came out. His work, however, received but scant attention, and 30 years later knowledge was put back over a century, when Stahl, failing to make the necessary distinction between matter and energy, introduced his phlogiston theory According to this conception, which dominated biology and chemistry for over a hundred years, when a substance burned, phlogiston departed from it, the body suffered a loss, it became dephlogisticated Stahl, rejecting the idea that animal heat was due to chemical action, returned to the old view that it arose from friction of the blood in the vessels, while his pupil Haller, writing only a few years before Hales died, denied that air entered into combination with the blood, so completely had the work of Mayow and Lower been neglected Not till 1754 did Black deal his death-blow to the phlogiston theory when he prepared carbon dioxide and not till 20 years after Hales's death, in his eighty-fourth year, did Lavoisier enunciate the true principles of respiration, combustion, and animal heat

Applying his "statical method," Hales demonstrated that plants absorb considerable quantities of "air" By distilling vegetable substances he showed that plants contained "air" He came to the con-

The ancient Savoy Palace, which stood in the Strand, is described in the early part of the eighteenth century as follows:—

' This *Savoy* House is a very great and, at this present, a very ruinous Building Its large Hall is now divided into several Apartments A Cooper hath a Part of it for stowing of his Hoops Other Parts of it serve for two Marshalseas for keeping Prisoners, as Deserters, men prest for military Service, *Dutch* recruits, &c. In this *Savoy*, how ruinous soever it is are divers good Houses "

These "good houses" comprised the Royal printing press a parish church, meeting places for a number of religious sects a prison, and "harbours for many refugees and poor people ' The Savoy prison had an evil reputation for the gaol distemper Regiments on service were terrified of receiving drafts of pressed men thence lest they brought the typhus with them. So in 1749 the following item of news appeared in an issue of the *Gentleman's Magazine*. The good Doctor, by desire of the secretary at war was this day at the Savoy prison, to direct a proper place for the erection of a large ventilator "



The windmill ventilator erected by Hales on Newgate by order of the Aldermen of the City of London in 1752

(*From a print in the British Museum*)

Hales's ventilators were also installed in the gaols at Northampton, Shrewsbury, Winchester. Maidstone Bedford and Aylesbury. in the London small-pox hospitals and at St. George's, also in hospitals at Durham Winchester and Bristol and even at Naples! Later they were introduced into the naval and military hospitals and prisons at Gosport. Portsmouth and Plymouth. So eventually even the Navy was convinced

"God be thanked" writes Hales "they are now come into general esteem for the apparent salutary good effect of them in our fleets, hospitals &c. In the beginning of the year 1756, the Lords Commissioners of the Admiralty ordered them to be put on board the *Royal George* our largest ship in which the honourable Admiral Boscawen, taking care to have them properly worked, they were found to have the desired good effect, so to refresh the whole air in the ship as to preserve in good health 850 men which happy event occasioned their being ordered to be put into the whole fleet "

Wherever Hales's ventilators were installed the air in the wards is said to have been rendered much purer, and the mortality among the inmates from the gaol distemper considerably reduced But typhus is due to the bites of infected lice, and not to foul air as Hales supposed No amount of ventilation however perfect, could have abolished the gaol distemper Hales's bellows ventilator has gone Hospitals and prisons are so built in these days that mechanical ventilation is seldom necessary. But his principle of the forcible propulsion of air still persists. and adequate ventilation remains one of the first principles of preventive medicine Hales must therefore stand for all time, not only a great biologist, but one of the pioneers in public health.

Hales also suggested that his ventilators should be applied to a number of other practical purposes, and particularly to the preservation of corn dry in granaries and therefore free from being eaten by insects At his instigation, Duhamel erected a large windmill ventilator over a public granary in Paris, which is said to have served its purpose very successfully. Hales also recommended their use for drying gunpowder. purifying "stinking water,' and ventilating mine shafts. He even adapted them for domestic use Thus to the Rev. Dr. Kerrich, Dr Pyle, Chaplain to George II . wrote as follows:—

"Dear Sir —The only articles of that sort, that I know of, are: That Dr. Hales hath actually published: what has been sometime talked of a tube of tin, with a box, of the same, at the lower end of it (like a box for a great seal), that is full of very small holes This engine, with the help of a pair of bellows, blows up cream into syllabub, with great expedition. This complex machine hath already procured the Dr the blessing of the housekeeper of this Palace, and of all such as she is, in the present generation (who know the time and labour required to whip this sort of geer). and will cause his name to be had in reverence, by all housekeepers, in the generations that are yet for to come.'

His reputation as a scientist was now international. His books had been translated into all the chief European languages In 1753 he was elected one of the eight foreign members of the Royal Academy of Sciences in Paris. Three years later war was declared with France England was unprepared but the French were quick in their attack. "A despondency without parallel in our history" wrote Green the historian. took possession of our coolest statesmen and even the impassive Chesterfield cried in despair '*We are no longer a nation.*'" Throughout these depressing years Hales laboured unceasingly to get Louis XV. to order the installation of ventilators into the French hospitals and prisons where British soldiers were confined Exerting all his influence through Duhamel and the Duc de Noailles he was at last successful, and his ventilators were installed into some at least, of the French gaols with it is said, considerable reduction in the death-rate among the British prisoners On this occasion the Minister of Teddington was heard to say that he hoped no one would inform against him for corresponding with the enemy' unsuccessful attempts himself to discover a safe solvent for the stone. So when Mrs. Stephens's medicines came along he was quick to put them to some sort of experimental test. Against his better judgment he persuaded himself of their dissolving power in vitro, and then, too readily, accepted the convincing testimony of the men of physic, in whose province, as he so often said, it was not for him to meddle. In 1739 he was awarded the Copley Medal of the Royal Society, not for his classical experiments on the physiology of animals and plants, but for the least successful and least creditable of all his scientific endeavours—his work on the calculus!

His Applied Science.

This episode, which had brought him both into public affairs and into the field of clinical medicine, seems to have been a turning-point in his work. Being intimately associated with a number of sea-faring persons, and learning the various hardships they were compelled to endure on long voyages, he determined, out of the benevolence of his disposition, to make a definite attempt to do something towards ameliorating the conditions of life of sailors at sea. So Hales now leaves his academic biology to become, as we shall see, a master of applied science. He invented methods of purifying distilled water and salting animals whole. He advocated the addition of acid to keep fresh water sweet, and the use of burning brimstone, not only for the prevention of "weevil and meggots" in ship's biscuit, but for preventing the rise and spread of "infectious distempers." Some of his methods, or the principles on which they were based, were not altogether original. Some of the practices he advocated were of doubtful utility. But the value of this work of his lay, not so much in what he did, but in the fact that he never ceased forcing scientific methods on the attention of the Admiralty. He must have been regarded as an intolerable nuisance at first, to be laughed at by some, scorned by others. To such treatment, however, he was happily immune. Whether the Admiralty actually adopted some or any of these methods he advocated is uncertain, but his insistence prepared the way for the acceptance of his great invention that was to follow.

His Ventilators

In 1740 troops lay embarked off Spithead for an expedition to America. Hales suddenly conceived the notion that large ventilators would be very serviceable in making the air in ships more wholesome. These ventilators were to take the form of large bellows to be worked by hand, which would suck out the foul air from between decks. But he was not alone in this idea. A few months later, Martin Triewald, Captain of Mechanics and Military Architect to the King of Sweden, devised a similar machine which was fitted on board the men-of-war that were sent to blockade St. Petersburg. As Hales remarked:—

> "It were indeed a very extraordinary Circumstance, that two Persons at so great a Distance from each other, without getting a Hint of it, one from the other, should happen to hit on inventing a like very useful engine."

But it was even more remarkable than this, because at the same time, Sutton, a coffee-house keeper in Aldersgate-street, contrived a method of drawing off the bad air on board ship by means of the cook-house fire. Sutton's invention remained in obscurity, but Hales's ventilator at once attracted the attention of the Admiralty.

> "Dr. *Lee* having heard of them, he first," writes Hales, "and then the rest of the *Right Honourable the Lords Commissioners of the Admiralty*, were pleased to send for me, to be further informed about them; and thereupon were pleased to order the Master Ship-Wrights, and other officers of *Woolwich* and *Deptford* Yards to consider the most commodious Place where to fix them on a Ship."

Accordingly, they were fitted on board H.M.S. *Captain*, a 70-gun man-of-war. His ventilators, however, were received with 'coolness by some, and contempt by others", it was probably too much trouble to work them. But if they did not find favour at first in the Royal Navy, they met with great success in convict ships and the vessels of the slave trade. The mortality on slave ships was appalling; many are said to have lost up to 50 per cent. of their slaves during voyages across the Atlantic, a death-rate which the installation of ventilators did much to reduce. Five Nova Scotia ships were equipped with them by the Earl of Halifax. Only one slave died in the ventilated ships for every 12 in those unventilated. In a letter to Hales, Captain Thomson wrote as follows:—

> "We found this good Effect, from Ventilation, that though there were near 200 Men on board, for almost a Year, yet I landed them all well in Georgia notwithstanding they were pressed Men, and delivered me out of Gaols with Distempers upon them. This is what I believe but few Transports, or any other Ships, can brag of; nor did I ever meet the Good-luck before; which, next to Providence, I impute to the Benefit received by Ventilators."

Dr. Demambray wrote:—

> "Ventilators were put into the Vessels in the Slave trade, at *Bordeaux*, and in other Ports of *France*, the happy Effect of which was, that instead of the loss of one-fourth of those valuable Cargoes, in long Passages from *Africa* to the *French* plantations, the Loss seldom exceeded a twentieth. And since my Return to *England*, I have been informed of a *French* Vessel, which by this self-evidently reasonable Precaution, saved 308 out of 312 Slaves, spite of most tedious Calms, and a long Passage."

Thus Hales did much to mitigate some of the horrors of the slave trade, but it is an interesting illustration of the mentality of his generation in respect of social reform, that, when preaching before the trustees of the Colony of Georgia, he confidently justified slavery as being in accordance with the teaching of Christianity!

The Ventilation of Prisons

Entering the city from the west, the traveller of those days must have been confronted by a curious spectacle. Newgate, the ancient gate of London, built by the executors of the celebrated Richard Whittington, thrice Lord Mayor of London, and only partially destroyed in the Great Fire, had been rebuilt with considerable magnificence.

> "It consisted of a carriage archway in the centre; on the side, the footpath was continued through it, which supplied a shelter for two or three old women, who fried small sausages for sale; and in the centre of it was an entry to the chief prison of the city; the mendicant prisoners for debt stood within the iron grated door, vociferating their constant supplication for benefactions to a leathern bag which they drew in as often as it was touched; the upper chambers of the buildings constituted the prisons for felons, for whom a door was opened on the South side adjoining the old wall, and it was from this door that the malefactors were received into the cart for their last journey to Tyburn. Upon the summit was a machine for air, invented by Dr. Hales."

In 1750 a tragedy had occurred during the trial of malefactors at the Sessions House in the Old Bailey. The Lord Mayor, two judges, and a total of 60 persons had died of the gaol distemper, communicated to them by the felons from Newgate! The aldermen of the City of London, naturally seriously alarmed, consulted Hales, and decided to instal ventilators in Newgate to be worked by a windmill erected on the "leads." During the construction of the ventilator the youngest of the journeymen on the work was forced to go down into the main shaft of the ventilator by his fellows to bring up a wig one of them had thrown down. As the windmill was working at the time, he nearly "died of the Stink" it is said, before they could get him up. That night this young man contracted typhus, and seven out of Mr. Stibbs's eleven workmen were striken with the same disease. When at last the system was complete Hales made a tour of inspection of Newgate, and rejoiced to see the ventilators, "drawing like large heavy lungs at the rate of seven thousand tuns of foul air per hour out of the different wards of the prison."

Registrar to enter No of Death Entry.

BIRTHS AND DEATHS REGISTRATION ACTS, 1836 TO 1926.

MEDICAL CERTIFICATE OF CAUSE OF DEATH

For use only by a Registered Medical Practitioner who has been in attendance during the deceased's last illness, and to be delivered by him to the Registrar of Births and Deaths direct

Name of Deceased . . . .

Date of Death as stated to me . . day of . 19 . . Age as stated to me . .

Place of Death . . . .

Last seen alive by me } day of 19 . Seen* / Not seen* } after death by me.

Post mortem held* / not held*

CAUSE OF DEATH

I Immediate cause†	*a*	. . .
Morbid conditions, if any, giving rise to immediate cause (stated in order proceeding backwards from immediate cause) .	*b* *c* .	. .
II Other morbid conditions (if important) contributing to death but not related to immediate cause		

I hereby certify that I was in medical attendance during the above named Deceased's last illness, and that the particulars and cause of death above written are true to the best of my knowledge and belief

Signature . . . . *Qualifications as registered by Medical Council* } .

Residence . . . . *Date* . . . .

* Strike out whichever is inapplicable
† This means the disease, injury, or complication which caused death—not the mode of dying, as, e g, heart failure, asphyxia, asthenia, &c

Immediate and Remote Causes

In a majority of cases only one cause of death need be stated and in these the form of the certificate is of little importance But where two or more causes are entered the distinction between "primary" and "secondary" is no longer called for, as it was found to give rise to confusion The present form of certificate is divided into two sections (I and II) In "I" should be entered the immediate cause of death and any morbid conditions which led up to it, the latter being stated in order backwards from the immediate to the remoter causes In "II" should be entered conditions which are not in the chain of pathological events which have led to the immediate cause of death but which have none the less contributed seriously to the fatal issue The seven examples here given are intended to make these points clear

When possible it should be stated in the certificate whether the condition was acute or chronic It is suggested that the practitioner should in each case first consider whether the essential features of the case cannot be epitomised by statement of a single cause—e g, pulmonary tuberculosis—and that where entry of more than one cause is required he should next consider whether the conditions specified were or were not of independent origin, and indicate this by entry in the appropriate space If either this distinction or that implied by order of entry under "I" cannot be made the fact should be stated

Seven Examples of Method of Using the New Form of Certificate

	Ex 1	*Ex 2*	*Ex 3*	*Ex 4*	*Ex 5*	*Ex 6*	*Ex 7*
I Immediate Cause	I (*a*) Lobar pneumonia	I (*a*) Puerperal eclampsia	I (*a*) Carcinoma of liver	I (*a*) Hæmatemesis	I (*a*) Acute peritonitis	I (*a*) Pyelonephritis	I (*a*) Bronchopneumonia
Morbid conditions if any, giving rise to immediate cause (stated in order proceeding backwards from immediate cause)	(*b*) — (*c*) —	(*b*) — (*c*) —	(*b*) Carcinoma of rectum (excised) (*c*) —	(*b*) Chronic gastric ulcer (*c*) —	(*b*) Intestinal perforation (*c*) Enteric fever	(*b*) Myelitis (*c*) Syphilis	(*b*) Operation (*c*) Strangulated inguinal hernia
II Other morbid conditions (if important) contributing to death but not related to immediate cause	II —	II —	II —	II —	II —	II —	II Chronic interstitial nephritis

Special Causes of Death

Some points arise in regard to special causes of death —

(*a*) *Cancer* —Attention is particularly directed

His Last Experiment.

In the year that the war began Hales performed his last experiment. He placed an equal number of gudgeon in two pails of pond-water; the water in one was ventilated with air, the water in the other allowed to remain stagnant. The fish in the former remained well, but those in the latter, the unventilated water soon "turned sick, came up for air and showed uneasiness, turned belly upwards, and then died." He commented on this experiment as follows:—

> "Hence we see the Benefit of frequently replenishing the Water with fresh Air, which we find is necessary not only to preserve the Life of Land Animals, but also of Fish, as also the Use of their Gills, to spread in thin Sheets fresh Supplies of Water, that they may the better come at the air in the water, for which Purpose both Sides of their Gills are furrowed with many fine Furrows, thereby to enlarge their Surfaces."

So at the age of 79 he returns from his applied science to his comparative physiology again, and after the lapse of 40 years completes his long series of experiments on respiration.

> "We have good reason," he writes "to be diligent in making farther and farther researches, for tho' we can never hope to come to the bottom and first principles of things, yet in so inexhaustible a subject, where every smallest part of this wonderful fabrick is wrought in the most curious and beautiful manner, we need not doubt of having our inquiries rewarded with some further pleasing discovery, but if this should not be the reward of our diligence, we are however sure of entertaining our minds after the most agreeable manner, by seeing in everything, with surprising delight, such plain signatures of the wonderful hand of the divine Architect, as must necessarily dispose and carry our thoughts to an act of adoration, the best and noblest employment and entertainment of the mind."

His Life's Work.

Hales was now over 80. He had advanced science by fundamental experiments on the circulation of the blood, the flow of sap, the chemistry of respiration, and the growth of bone. By his work on ventilation he had established one of the first principles of preventive medicine. He had ministered faithfully to his parish for over 50 years. In the last scene of his active life, we see him triumphant, reducing the mortality among British prisoners exiled in the gaols of France! Thus did Hales serve science and humanity, his King and his Country—service immortalised by Alexander Pope:—

From Peer or Bishop 'tis no easy thing
To draw the Man who loves his God, or King:
Alas! I copy (or my draught would fail)
From honest Mah'met,* or plain Parson Hale.

"Hales delighted to promote the honour of his God by advancing the best welfare of mankind," writes Butler. "In this employment, blessed with serenity of temper, he calmly met his death as an acquaintance long familiarised to this mind." Stephen Hales died at Teddington on Jan. 4th, 1761, in the eighty-fourth year of his age. His monument stands in Westminster Abbey, but his body lies buried, according to his own wish, under the tower which he had built himself, for the church he had loved so well. The inscription on the stones of the floor of the tower records the simple facts of his life and death but there is no epitaph written on his grave. To-day, however, 250 years after the birth of this great son of this College, let us adapt the words John Wesley wrote of him: "How well did Science and Religion agree in this man of sound understanding!"

---

* Mah'met, a Turkish servant to the King, whom he took at the siege of Buda, and constantly kept about his person.

QUEEN MARY'S HOSPITAL FOR THE EAST END.—The Lord Mayor of London last week laid the foundation-stone of a new wing which will be a memorial to the late Dr. P. J. S. Nicoll, who for many years was chairman of the honorary staff and vice-chairman of the hospital. The extensions will provide 32 additional beds, 24 of which are intended for adult casualties, a new ward for children, and a solarium for which Dr. Nicoll had raised a large sum before his death.

DEATH CERTIFICATION

THE NEW FORM OF MEDICAL CERTIFICATE

WITH the coming into force of the Births and Deaths Registration Act (1926) on July 1st next a new form of medical certificate is being issued for the use of registered practitioners. The new form of certificate has been drawn up after consultation between the Registrar-General and representatives of leading bodies in the medical profession with the object of making the official records of the causes of death a more exact summary of the opinions expressed in the certificate than hitherto. The essential part of the certificate is reproduced on the opposite page. On the left of this certificate form is a counterfoil for use of the medical attendant, on the right is the notice to informant that a medical certificate of the cause of death has been signed. The book in which these certificates are bound contains notes and suggestions to certifying medical practitioners.

The Certifier.

No medical certificate of cause of death may be given on the prescribed form unless the certifying medical practitioner has been in attendance upon the deceased during his or her last illness. The certificate must be given and signed by the practitioner who has been attending the deceased during the last illness, and no other person or practitioner may sign the certificate on his behalf. A registered medical practitioner who was in attendance upon a deceased person during his or her last illness is required to give a medical certificate of cause of death on the prescribed form in every case.

The Cause of Death.

The cause of death as certified by the practitioner in attendance during the last illness is entered by the registrar in the death register and forms part of that record. The entry in the death register and the certificate of cause of death itself are also utilised as material for the mortality statistics published by the Registrar-General. The value of these statistics will be materially enhanced if certifying medical practitioners will (*a*) read and adopt, so far as possible, the suggestions printed below, and (*b*) write the names of diseases (*in full*) in the certificates as legibly as possible, to avoid the risk of their being incorrectly transcribed into the death register. In view of the importance for many public purposes of the mortality statistics based upon these certificates, the Registrar-General hopes that he may rely upon the cooperation of the medical profession in these matters.

Use of Precise Terms.

It is desirable that medical practitioners should employ as far as possible only those terms recognised in the Nomenclature of the Royal College of Physicians of London. The use of vague and ill-defined terms is particularly to be avoided. An alphabetical list of such terms is appended,[1] with comments indicating in what respect the term is unsatisfactory and what further information as to the cause of death is required in each case. A few unobjectionable terms are included in the list for special reasons. This list is intended for reference only, and it is hoped that it will be consulted by certifying practitioners in any case in which they are not assured that the term used by them is included in the nomenclature of the Royal College of Physicians.

In cases where an indefinite term has to be employed because more definite information is lacking it would be well to indicate this fact in the certificate. The word "idiopathic" will be understood as indicating that the probable cause of the condition stated is unknown—e.g., idiopathic atrophy, idiopathic convulsions, idiopathic peritonitis, &c.

---

[1] An extract of this list was given in THE LANCET of Feb. 12th, p. 359.

the soaking of the clothes with sweat during work and the change from the warmer mine to the colder surface above, pithead baths should do much to remedy both this and the excessive work given the housewife by the men bringing dirt into their homes and requiring hot baths Colliery stacks gave off much black smoke, especially where there were draught furnaces, no improvement was likely to result from the Smoke Abatement Act, 1926

Dr G Q **Lennane** (M O H , Battersea), dealing with the hygiene of flueless gas stoves, pointed out that their ventilating effect was nil ; further legislation was required prohibiting their use in dwelling rooms

Diphtheria Carriers

Dr J E **McCartney** (Director of Research, Metropolitan Asylums Board) spoke on diphtheria carriers He and Dr W C Harvey took as their criterion the presence of virulent diphtheria bacilli 12 weeks after the onset of the disease Before a case was discharged six consecutive negative swabs should be taken over a period of three weeks Among 1000 patients they had found 8 7 per cent of carriers , in another series of 1080, 8 2 per cent Organisms disappeared more rapidly from the throat than from the nose The age of the patient was important, carriers were more common in the first seven years of life Intermittent carriers were found By far the most of the carriers had recovered from their illness, and only 18 per cent showed any general debility If anything, severe cases were less liable to become carriers than others The carrier condition was due to failure of the normal process of getting rid of the bacilli , there was no evidence of difference of the bacterial flora in carriers and others, nor of an alteration in the biological character of the diphtheria bacilli The nasal element was very important, most of the nasal carriers were under 5 years of age, and had suffered from purulent rhinitis , in only eight out of 185 cases was a pathological lesion absent When rhinorrhœa disappeared the bacilli disappeared too, returning when the rhinorrhœa came back The antibody content in the blood of carriers was high , evidently the bacilli lived outside the human body on inflammatory products As regards treatment, when the bacilli were limited to the throat tonsillectomy brought about cure in 100 per cent of cases , the intricacy of the nasal passages in young children made it difficult to reach them from without, and they must be treated by autogenous vaccines made from the organism causing the inflammation, usually the pneumococcus or hæmolytic streptococcus Nasal douching was useful both to prevent and to remedy the condition

School Medicine

An interesting discussion on school medicine resulted from the papers of Dr **Dunstan Brewer** (M O H , Swindon), Dr J F **Blackett** (M O H , Bath), and Dr **Charbonnier** (St Josse ten Noode)

Dr **Brewer** pointed out that the aim of school medicine was not to patch up things which had gone wrong , what was needed was the physiological measurement of the phenomena of child life Dr **Blackett** said that, unfortunately, the criterion in school medicine to-day was the child's ability to take advantage of the education offered it and not his health The work should be primarily preventive Might it not be better to build a house to replace a slum dwelling rather than maintain four beds at a sanatorium? Although school doctors perhaps could not do research with a big " R," he thought that they were quite capable of cooperative research with clinicians medical statisticians, and pathologists — Dr **Charbonnier**, with other speakers, held that the school doctor should be a man of considerable experience There were many difficulties in school medicine and it was absurd that such work should be undertaken by the comparatively recently qualified —Dr G F **Buchan** (M O H , Willesden) remarked that while it was easy to diagnose a case of lobar pneumonia, it was extremely difficult to diagnose the conditions which had led up to a state of malnutrition. —Dr P **Lomry** (Belgian Ministry of Health) thought that the forcing of the intellects of young children was responsible for much ill-health and even fatal disease

Health Propaganda

The merits of public health propaganda gave rise to a lively discussion Dr L **Delattre** (Belgian Ministry of Health) considered that even the most humble classes of the community could be reached by instruction The public authorities could thus enable the people to avoid or reduce many illnesses. and interest would be aroused in the public health institutions The most valuable means of instruction were the Red Cross, the elementary school and the trained nurse —Dr K E **Tapper** (M O H , Bromley) said that in certain forms of health publicity half-truths were being exploited which to-morrow might prove fallacies , this called for a control of all health publicity The propaganda of so many societies was only leading to chaos in the public mind. —Dr C S **Thomson** (M O H , Deptford) held that it was the duty of those in charge of the public health to teach the people —Dr J R **Kaye** (M O H West Riding) said that very successful health crossword puzzles had been used in his schools Other speakers were doubtful whether the general population gathered very much from health lectures and addresses

Milk, Water, and Meat Supplies

Mr **Wilfred Buckley** (Chairman Clean Milk Society) asked for half-yearly inspection of cattle by whole-time veterinary inspectors in order to eliminate tuberculous milk He held that persons adulterating milk and defaulting wholesalers should be legally debarred from selling milk All milk sold should be classified in a way understandable by the purchasers, the price varying according to the quality —Dr **Kaye** was very much opposed to pasteurisation. and this measure was objected to by others as militating against the adoption of cleanly methods

Dr J J **Paterson** (M O H East Berks U S D). referring to the many town workers who slept in the country, said that they required much more water than the ordinary rural population The legal powers of a rural sanitary authority were at present inadequate The area of supply of a water company was limited by purely artificial boundaries fixed long before housing schemes were dreamt of and the company was under no obligation to supply water to a house or group of houses unless it " paved " Local territorial water boards were wanted —Mr L **Gillet** and Mr C **Guillaume** spoke on the value of determining the chlorides in connexion with the potability of water , the presence of more than an easily ascertained quantity was a safe index of pollution

Prof J T. **Share-Jones** (Director of Veterinary Studies, Liverpool University), speaking on animal industry and public health said that eventually the U S A would compete with Great Britain for the meat products of the Argentine He asked for a State-aided system of live stock insurance, in order that investors might be disposed to put more money into the industry in this country Out of such an insurance would grow measures for the prevention of disease among cattle

Dr E **Sacquépee** (Medical Inspector French Army) pointed out the value of a continuous medical supervision of army cooks during epidemics especially of intestinal diseases —Dr **Dequidt** (Inspector-General of Hygiene, France) and Prof **Rochaix** (Lyons) went into the administrative arrangements in various countries for dealing with " carriers "

INDUSTRIAL HYGIENE

In a presidential address to the Section of Industrial Hygiene, Viscount **Leverhulme** said that at Port Sunlight accidents were less frequent during periods of greatest employment • probably when employment was good the individual worked with greater to the request that the seat of primary occurrence should be returned in all cases where known

(*b*) *Childbirth* —Whenever parturition or pregnancy has been in any way a contributory cause of death, the fact should be mentioned on the certificate All diseases arising therefrom should be described as puerperal—e g , puerperal eclampsia, puerperal septicæmia, distinguishing in the latter case between septicæmia originating in abortion and in childbirth

(*c*) *Violence* —The following suggestions as to the form of certification of deaths from violence, which for this purpose includes all deaths from unnatural causes (including anæsthetics and poisons of all forms), whether accidental, suicidal, or homicidal, are extracted from the Registrar-General's Circular to His Majesty's Coroners (1911) —

> " In every case of death by violence or by suspected violence, whether the death resulted from the violence itself or from a pathological state induced by it, the verdict should state the form and means of violence, its accidental, suicidal, or homicidal nature, and the nature of the injury—e g fracture of skull (*nature of injury*) due to being *accidentally run over* (*form of violence*) by a motor-car (*means of violence*) "

(*d*) *Anæsthetics* —When death occurs during anæsthesia, or is in any degree attributable thereto, the nature of the anæsthetic used should be recorded

Reporting to the Coroner.

On the back of the certificate form is provision for two additional statements, to be filled up by the doctor in any case where they apply The first relates to informing the coroner The law as stated in Jervis on Coroners provides that —

> " In all cases of sudden death or death under any circumstances of suspicion where the duty of informing the Coroner is not by Statute imposed upon any particular person, it is the duty of those who are about the deceased to give immediate notice to the Coroner or his officer or to the nearest officer of police, who then communicates with the Coroner "

Where a practitioner who was in attendance during the deceased's last illness gives notice in accordance with the obligation above described he should, on giving the certificate of cause of death, initial the Statement A on the back of the certificate

Obligation to Give a Certificate

Some doubts have existed as to the duty of practitioners to give certificates of cause of death in a case where an inquest may possibly take place It is desired to point out that, as the law now stands, the duty placed upon a registered medical practitioner who was in attendance upon a deceased person in his or her last illness to give a medical certificate of the cause of death to the best of his knowledge and belief, appears to be unqualified, and unaffected by the fact that he or some other person has reported the case to the coroner or that an inquest may take place

The practice of refraining from giving a medical certificate of cause of death when the case is being reported to the coroner was to some extent strengthened by the fear that, if a medical certificate is given, the death may forthwith be registered and the body buried before an inquest can take place Statement A on the back of the certificate has accordingly been included to obviate any such risk If the practitioner when giving a certificate is also reporting the case to the coroner and accordingly initials Statement A on the back of the certificate, it will be the duty of the registrar to suspend the registration of the death until he learns from the coroner whether an inquest is or is not to be held

Additional Information

Cases are understood to occur where the practitioner, when certifying the cause of death, is aware that some post-mortem or laboratory examination is about to take place or is in progress, from the results of which some further information may become available which will be of value for statistical purposes Provision is accordingly made in Statement B on the back of the certificate whereby the practitioner may give an indication that he may be in a position, if applied to later by the Registrar-General, to furnish additional information for statistical purposes On the receipt by the Registrar-General of a certificate on which the practitioner has initialled Statement B, the Registrar-General will in due course address an inquiry to the practitioner in order that the latter may communicate any further information with respect to the death which he may then be able and willing to give.

Medical Officers of Institutions

In certain cases deceased persons whose death took place in an institution are certified on the medical certificate of cause of death as " not seen after death " for the reason that, although such persons may in fact have been seen after death by *some* medical officer of the institution, they were not seen after death by the medical officer by whom the certificate was actually signed The latter is recommended to cross out the words " not seen " and " me " in the statement—

" Seen
Not seen } after death by me "

and write underneath those printed words the name of the medical officer by whom the deceased was seen after death The certificate will then read—" Seen after death by Dr So and So "

ROYAL INSTITUTE OF PUBLIC HEALTH.

THE CONGRESS AT GHENT

THE annual Congress of the Institute was held at Ghent, Belgium, from June 1st to 6th under the presidency of Viscount BURNHAM The King and Queen of the Belgians were present at the inaugural meeting

Honorary degrees were conferred by the University of Ghent upon Sir Berkeley Moynihan (President of the Royal College of Surgeons of England), Lord Burnham, and Sir William Smith (senior Vice-President and Principal of the Institute)

PROBLEMS OF PUBLIC HEALTH

The subjects considered by the Section of State Medicine covered a large field

Dr MARY SHARE-JONES (A M O H , Denbighshire) discussed how far State interference in personal matters was justifiable She had found that the objection to vaccination was not intelligent but a mere stubborn display of freewill , legislation on vaccination was more forceful in other countries Notification of tuberculosis was very lax in some areas As regards housing to-day, there was a widespread demand for the withdrawal of State interference, but a compromise between this and private enterprise was wanted The absence of provision for compensation was a weakness in the Meat Regulations, and invited certain owners of animals to conceal disease

Dr W A MURPHY (M O H , Ogmore and Garw U D C) dealt with the sanitary problems of a colliery district The mining valleys in South Wales, he said, were so narrow that hillsides had to be excavated for housing sites, which added £50 to £100 to the cost of each house River pollution, due to the coal washings and the actual mine refuse falling into the rivers, was general Subsidence due to undermining broke the continuity of all pipes and caused the windows to jam The best type of owner felt discouraged because he was compelled to rebuild the house at the expiry of the lease Compensation should be payable The local sanitary authorities had no control over the sanitation of the mines , below ground the miners used the gobs or wastes for depositing dejecta, and probably the drinking of mine water accounted for sporadic cases of typhoid fever The death-rate from bronchitis in mining areas was much higher among males than females , this was probably due to chilling brought about by units on the march Six seats were provided for every 100 men; protection from rain was afforded by impermeable canvas He pointed out the waste of money entailed by erecting temporary latrines for a fortnight's camp, the use of shallow trenches was very objectionable Much illness in the army was due to constipation caused by reluctance to use unsatisfactory sanitary accommodation.

Selection of Airmen

Wing-Commander T S RIPPON dealt with methods of examination of airmen which did not require elaborate apparatus Personality was studied in conversation about the candidate's habits, amusements, likes and dislikes, the questions being founded on a knowledge of the temperament of the successful pilot Mental tests were then employed These included the time taken to play a single-handed game of dominoes (a very good time being 50–55 seconds) Visual apprehension was tested by exposing a group of ten familiar objects for six seconds, after which they were enumerated by the candidate, the average result was seven correct Reflex reaction time could be estimated by visual auditory or tactile signals, these were not found very useful if used alone, but when the candidate was given a choice of two or more signals and instructed to reply to one only, a higher correlation with flying ability was obtained If a sudden loud noise was added to the test, a satisfactory method of grading pupils under instruction was obtained

Undulant Fever and Malaria

Sir PERCY BASSETT-SMITH considered that no relationship between undulant fever and the epidemic abortion of animals had been established Undulant fever occurred originally on the Mediterranean littoral, from which it had spread inland A French Government Commission had found that the disease, which formerly affected three provinces only, had now spread to 13, the infection of sheep was almost as great as that of goats. Epidemic abortion, however, had affected cattle and pigs in a very much larger area of France, there were thus epidemiological differences between the two diseases Although the organisms were somewhat similar, considerable distinction even in morphology could be made between them. The abortus organism was confined to the genital tract; clinically a very massive dose was required to produce disease in man, whereas it was difficult for a laboratory worker to escape infection with the undulant fever organism It was very rare for any woman with undulant fever to abort

Dr A. BRODEN had found plasmochin valuable for malaria patients sent home from the Congo Patients infested with *Plasmodium vivax* were rapidly cured with plasmochin alone; those with *P falciparum* and gametes responded equally quickly to treatment with a mixture of plasmochin and quinine

The other Sections of the Congress were devoted to Pathology, Bacteriology, and Biochemistry, and to Women and the Public Health A very large number of subjects were considered

CHINA

(FROM OUR OWN CORRESPONDENT)

Shanghai and the Defence Force

NOT often has the British Army been called upon to face a more difficult situation than now confronts the Defence Force at Shanghai In combination with Japanese, American, French, Italian, Spanish, and Portuguese units, as well as the International Volunteer Corps, our troops since landing have been guarding a city which is never ttacked and, now that the Chinese have noted its strength is not likely to be With this inaction it is no small task to keep the men constantly keyed up to fighting pitch, especially in such surroundings The boundary is marked by barbed wire fences within which, in an area of 8⅔ square miles with a foreign population of 23,100 and 802,700 Chinese—in other words, a density of 149 persons per acre—our 10,000 troops, in addition to those of other nations and a large number of commercial and missionary refugees, have had to find quarters From this it will be seen why the authorities have been hard put to it to meet the heavy civil and military requirements

Shanghai is fortunate in the possession of a very efficient municipal health department, at the head of which is Dr Noel Davis, under whose watchful eye the problems of sanitation and preventive medicine are being constantly studied and dealt with Since the arrival of the British troops there have been many cases of influenza and pneumonia, but the question of venereal disease has been the most clamant one, and in spite of every possible precaution the number of those affected has steadily increased The community has risen to the occasion and a great deal of very meritorious work has been done, notably by the British Women's Association, in opening recreation centres Football, hockey, and cricket fields have been provided and there are various clubs to which soldiers are made welcome No young soldier need lack for friends and entertainment, but in spite of all this care there are, unfortunately, ample opportunities of infection Numbers of prostitutes from north and south have flocked to Shanghai, most of them being Chinese (60 per cent), Russians (30 per cent), and Japanese (5 per cent) The majority of the brothels are in the French Concession and in Chinese districts bordering on municipal roads The high venereal rate has given the Command much concern and no stone is left unturned in the effort to lower it

The present cool spring is the healthiest time of the year Soon, however, the hot weather will set in and the authorities will have to face a momentous problem in maintaining the health of the Forces An important division of the work is that of inoculation and vaccination against the diseases endemic in Shanghai There is a field hygienic section and a sanitary section under Royal Army Medical Corps public health specialists with N C O's and men who are trained inspectors and are quick to see where faults need remedy Intensive health propaganda is going on throughout the Force, in addition to the work of inspecting, advising, and improvising A careful system of chlorination is carried out in each billet to safeguard the water-supply Mosquitoes swarm during the summer months and a net will be issued to each soldier, veils are to be worn by men on sentry duty. Flies will also come under ban as far as possible, food is to be kept in fly-proof safes and each unit is being provided with fly sprays for use in billets Chinese cooks are being carefully supervised and all food given to the Force is inspected by qualified members of the different units No cook can expect to retain his post unless he submits to examination to show whether he is a disease-carrier or not Electric fans are being provided and heat-stroke stations are being erected at which the troops can receive first-aid treatment, by application of ice caps, until they can be taken to hospital There is a health and sports section at Divisional Headquarters following the same lines as those worked out for the Army in India

It will thus be seen that the authorities are doing their very best for the soldier, who has a difficult psychological part to play in maintaining himself in a state of constant readiness to meet attack The whole political situation is too chaotic to admit of any intelligent anticipation, but there is every indication that no attempt on the Settlement is contemplated by the Chinese Generals of either side while our troops are here It may be said of the Shanghai Defence Force that it will not be needed till it has left Its advent undoubtedly saved the city.

The Military Hospital.

In a comparatively short time a modern office and apartment building has been transformed into a well-equipped and commodious 300-bed military hospital for British troops Wards for officers and deliberation On Mondays and Tuesdays the highest number of accidents occurred, then came Fridays, less occurred on Wednesdays and Thursdays The largest percentage of accidents were found amongst workers over 40 years of age, possibly because familiarity bred contempt Music had been introduced into departments where monotonous work, such as stamping, wrapping, and packeting of goods was carried on Factory girls, unfortunately, had no opportunity of learning housekeeping and the care of children before marriage, and employers would be doing a national service by supplying them with facilities

Cancer

A discussion on industrial cancer was opened by Dr A **Leitch** (Director of the Cancer Hospital Research Institute, London) and Dr R **Prosser White** (Wigan) Dr **Leitch** pointed out that persons exposed to influences conducive to cancer might develop the disease long after leaving their occupation He thought that Kashmir cancer was due to the influence of heat alone, all its victims showed multiple cicatrices, and there was no evidence of any influence of charcoal fumes Cancers due to single traumata occurred, but were rare He referred to a case of epithelioma of the skin inside the nostril, which had started 16 days after splashing with a spot of tar, many experiments had been made by dropping hot tar once on the back of mice, but it was very unusual for cancer to develop The tendency in Belgium to produce low temperature tars should help towards prevention of tar cancer, the lower the temperature at which tars and mineral oils were distilled the less was the tendency to produce cancer It was only when the tar from splint coal used in Scotland was distilled at high temperatures that it caused cancer He did not believe in an inherent disposition of an individual to contract the disease Nor was he convinced that oil need be locally applied to produce cancer of the scrotum, this part of the body was so sensitive that all that was necessary was for a minute portion of oil to reach the scrotum somehow In chimney-sweeps' cancer only an infinitesimal portion of soot reached the scrotum, again, only a small portion of this soot was soluble in sebaceous material, and it took years and years of this effect to produce the cancer Dr Leitch referred to the absence of mule-spinners' cancer when sperm oil was used, this oil was expensive, and efforts were being made to elaborate a suitable harmless vegetable oil which would be more widely used

Temperature and Humidity.

Mr S **Wyatt**, who is working for the Medical Research Council, gave instances of the deleterious effect of high temperature combined with humidity on the efficiency of workers Among tin-plate workers the output was 13 4 per cent less in the hottest month of the year than in the coldest month In the coal mining industry the most favourable temperatures and humidity for work occurred when the dry bulb registered 73 5° F and the wet bulb 66° F, only 59 per cent of this output was produced when the dry bulb registered 86 2° F and the wet bulb 79° F Industrial accidents were more frequent at high temperatures, the optimum being about 67° F, at 77° F the frequency was 23 per cent, and at 57° F 16 per cent greater Vernon and Bedford, examining the absences on account of sickness among women employed in six different departments of a factory, found that in one department, where the temperature was comparatively low, the loss of time during absence was greater in the winter months than in the other departments; a similar phenomenon occurred in the summer Increased air movement by means of fans would do much to produce cooling in factories It had been shown that if the cooling power of the naked skin were taken as 100, it was reduced to 73 by the wearing of a woollen vest the addition of a linen shirt brought it down to 60, whilst the wearing of a coat as well further reduced the cooling power to 46 Many industrial workers were overclad, they should have the arms, neck, and as much as possible of the chest and body bare, the garment should be loose and of loose texture

A paper by Prof C P. **Vaglou** (Harvard) dealt with experiments with two conditioning rooms in which the warmth, humidity, and air movements could be varied Many thousand trials had been made by factory employees wearing their working clothes, first they entered one room, and then the other, where the conditions had been adjusted to vary slightly, and then they were asked which they preferred From the results of these observations an "effective" temperature chart had been prepared The sensations of one temperature could be obtained at another temperature by adjusting the humidity and the air movement The comfort zone was at a much higher temperature when the workers were partly stripped —Prof E L **Collis** thought that although, for scientific purposes, the "effective" temperature chart would be valuable, in actual practice the kata-thermometer would still be widely used because of the difficulty of determining air movements at low velocities by anemometers, indeed, the kata-thermometer was the best anemometer under these conditions

Firedamp

In the course of a discussion on the hygiene of mines Dr **van Hassel de Paturage** said that firedamp was not poisonous in itself, it was only dangerous when it replaced the oxygen It might come out slowly from the coal or erupt suddenly, causing forcible projection of coal dust, rock, and pieces of wood Mixtures of 6 to 17 per cent of firedamp with air were explosive The miners might be injured by the projectiles, they might be burnt when the gas caught fire, and they might be asphyxiated by the carbon monoxide formed He emphasised the value of subcutaneous injections of oxygen, which should be given by a trained lay personnel, while the men were still down the mine, and described an apparatus he had invented for the purpose —Dr **Roels** thought that injections of lobeline should be tried —Prof **Collis** mentioned the apparatus recently brought out by Prof J S Haldane, much used in America and England, in which the oxygen administered was mixed with 4 to 5 per cent of carbon dioxide to stimulate the bulbar centres

Naval, Military, Air, and Tropical Diseases

At the section devoted to these subjects a paper on the maintenance of satisfactory air temperatures in living and working spaces in ships in the British Navy was read by Surgeon-Captain T B **Shaw**, and considerable time was given to health problems of the mercantile marine

Dr **Vigné** (Le Havre) pointed out the importance of preventing any tuberculous person entering the mercantile marine, the personnel should be inspected before every voyage by the ship's doctor (or in ships not carrying doctors by the port authorities) Tuberculosis was produced by the conditions of sea life, and there ought to be an insurance scheme so that any seaman discharged on account of tuberculosis should have monetary assistance to enable him to work at some other occupation

Dr R **Bernard** (Brussels) and Mr M **Haeck** (Ostend) outlined the arrangements necessary for wireless consultations at sea While avoiding any attempt at "treatment by correspondence," patients when at sea could be helped by radiotelegraphy Messages could be sent enormous distances by a system of relays, but first international agreement would have to be reached A code would not serve, and specially internationalised radiotelegraphic formulas would have to be devised; a special wavelength should be reserved for the purpose

Lieut -Colonel C F **Searle** showed a model of a portable field latrine which could be used even by units on the march Six seats were provided for every 100 men, protection from rain was afforded by impermeable canvas He pointed out the waste of money entailed by erecting temporary latrines for a fortnight's camp; the use of shallow trenches was very objectionable Much illness in the army was due to constipation caused by reluctance to use unsatisfactory sanitary accommodation.

Selection of Airmen

Wing-Commander T S RIPPON dealt with methods of examination of airmen which did not require elaborate apparatus Personality was studied in conversation about the candidate's habits, amusements, likes and dislikes, the questions being founded on a knowledge of the temperament of the successful pilot Mental tests were then employed These included the time taken to play a single-handed game of dominoes (a very good time being 50–55 seconds) Visual apprehension was tested by exposing a group of ten familiar objects for six seconds, after which they were enumerated by the candidate, the average result was seven correct Reflex reaction time could be estimated by visual auditory or tactile signals, these were not found very useful if used alone, but when the candidate was given a choice of two or more signals and instructed to reply to one only, a higher correlation with flying ability was obtained If a sudden loud noise was added to the test, a satisfactory method of grading pupils under instruction was obtained

Undulant Fever and Malaria

CHINA.

(FROM OUR OWN CORRESPONDENT)

Shanghai and the Defence Force

NOT often has the British Army been called upon to face a more difficult situation than now confronts the Defence Force at Shanghai. In combination with Japanese, American, French, Italian, Spanish, and Portuguese units, as well as the International Volunteer Corps our troops since landing have been guarding a city which is never ttacked and, now that the Chinese have noted its strength, is not likely to be. With this inaction it is no small task to keep the men constantly keyed up to fighting pitch, especially in such surroundings. The boundary is marked by barbed wire fences within which, in an area of 8⅔ square miles with a foreign population of 23,100 and 802,700 Chinese—in other words, a density of 149 persons per acre—our 10,000 troops, in addition to those of other nations and a large number of commercial and missionary refugees, have had to find quarters From this it will be seen why the authorities have been hard put to it to meet the heavy civil and military requirements

Shanghai is fortunate in the possession of a very efficient municipal health department, at the head of which is Dr Noel Davis, under whose watchful eye the problems of sanitation and preventive medicine are being constantly studied and dealt with Since the arrival of the British troops there have been many cases of influenza and pneumonia, but the question of venereal disease has been the most clamant one, and in spite of every possible precaution the number of those affected has steadily increased The community has risen to the occasion and a great deal of very meritorious work has been done, notably by the British Women's Association, in opening recreation centres Football, hockey, and cricket fields have been provided and there are various clubs to which soldiers are made welcome No young soldier need lack for friends and entertainment, but in spite of all this care there are, unfortunately, ample opportunities of infection Numbers of prostitutes from north and south have flocked to Shanghai, most of them being Chinese (60 per cent), Russians (30 per cent), and Japanese (5 per cent) The majority of the brothels are in the French Concession and in Chinese districts bordering on municipal roads The high venereal rate has given the Command much concern and no stone is left unturned in the effort to lower it

The present cool spring is the healthiest time of the year Soon, however, the hot weather will set in and the authorities will have to face a momentous problem in maintaining the health of the Forces An important division of the work is that of inoculation and vaccination against the diseases endemic in Shanghai There is a field hygienic section and a sanitary section under Royal Army Medical Corps public health specialists with N C O's and men who are trained inspectors and are quick to see where faults need remedy Intensive health propaganda is going on throughout the Force, in addition to the work of inspecting, advising, and improvising A careful system of chlorination is carried out in each billet to safeguard the water-supply. Mosquitoes swarm during the summer months and a net will be issued to each soldier; veils are to be worn by men on sentry duty. Flies will also come under ban as far as possible, food is to be kept in fly-proof safes and each unit is being provided with fly sprays for use in billets Chinese cooks are being carefully supervised and all food given to the Force is inspected by qualified members of the different units No cook can expect to retain his post unless he submits to examination to show whether he is a disease-carrier or not. Electric fans are being provided and heat-stroke stations are being erected at which the troops can receive first-aid treatment by application of ice caps, until they can be taken to hospital There is a health and sports section at Divisional Headquarters following the same lines as those worked out for the Army in India

It will thus be seen that the authorities are doing their very best for the soldier, who has a difficult psychological part to play in maintaining himself in a state of constant readiness to meet attack. The whole political situation is too chaotic to admit of any intelligent anticipation, but there is every indication that no attempt on the Settlement is contemplated by the Chinese Generals of either side while our troops are here. It may be said of the Shanghai Defence Force that it will not be needed till it has left. Its advent undoubtedly saved the city.

The Military Hospital.

In a comparatively short time a modern office and apartment building has been transformed into a well-equipped and commodious 300-bed military hospital for British troops Wards for officers and men, executive offices, operating theatres and adjoining surgical rooms, X ray equipment, laboratories, dispensary, dental clinic, living quarters for R.A.M.C. personnel—all of which are now comprised in the building's eight floors—make it difficult to think of the place as designed for any other purpose. An adjoining corner of land is rapidly being prepared as a recreation ground for patients. Partitions throughout the entire building were knocked down and three- and four-room apartments had their dividing walls removed to make the long wards. X ray work is done by a Solus portable apparatus which is mounted on a trolley, can be moved from one ward to another, and is noiseless when taking pictures. The fourth floor contains wards for acute medical cases, also a special ward for pulmonary isolation cases. The main surgical ward is on the fifth floor, together with the operating theatres. Officer patients are on the sixth floor in smaller wards and the hospital staff is housed on the seventh floor, while the kitchens are on the eighth floor where there are also dining and recreation rooms. The present staff represents only one-third of the actual unit, which is known as No. 7 British General Hospital; two-thirds of the staff and equipment are still at Hong-Kong. Brevet-Colonel E. Ryan, D.S.O., is in command. Another section of 200 beds will shortly be opened in the Polytechnic Public School, and accommodation is being sought for a further 100 beds. When the hot weather arrives and the disease-rate rises another general hospital will be available, as it has already left England. A large number of sick have already been admitted to the Country Hospital, a palatial new building embodying all the advantages of a modern hospital and recently put up by an Englishman who presented it anonymously to the Shanghai community for the use of all nationalities. Arrangements have been made for hospital accommodation in Vancouver for convalescents during the hot weather; but, if for nothing else than the sake of the British ratepayers' purse, it must be hoped that advantage will be taken of coastal health resorts in North China such as Wei-hai-wei, Shan-hai-kuan, and Peitai-ho, the use of which would obviate the long and costly journey to Canada and back.

ROYAL MEDICAL BENEVOLENT FUND

AT the last meeting of the Committee 36 cases were considered and £690 voted to 34 applicants. The following is a summary of some of the cases relieved.

L.R.C.P., aged 82, widower, one daughter, aged 33, teacher of piano and violin. Applicant had to give up practising on account of age and deafness. His savings with those of his daughter's were invested in purchasing the house they now live in. They have let three rooms receiving 25s. a week in rent. Apart from this applicant has the Old Age Pension and the daughter receives £20 as an organist. She has no pupils at present. Interest on mortgage £24 per annum. Ground rent £7, rates £20. Voted £10 in 12 monthly instalments.

Daughter, aged 79, of M.R.C.S. who died in 1885. She suffers from rheumatism and has cataract on both eyes. She has two pensions, one of which is the Old Age Pension, these amount to £66 per annum. £5 is received from investments and £65 from letting. Applicant's sister died last month and was an annuitant of this Fund. Voted £20 in 12 monthly instalments.

Daughter, aged 50, of M.R.C.S. who died in 1880. Only employment is rent collecting, from which she receives about £63 per annum. Other income £5 from investments. Rent 7s. 6d. per week. Unable to get additional work on account of ill health. The Fund helped this case in 1913 to enable the applicant to have typewriting lessons. Voted £26 in 12 monthly instalments.

Son, aged 16, of M.B. Glasg. who died in 1921. Mother is in a mental hospital. The boy is in charge of an uncle who is not able to keep him entirely. He earns 10s. a week as an engineer's apprentice. Fund repeated the grant of £26 towards his maintenance.

Son, aged 3, of L.R.C.P. who died in 1926. This boy, with his two elder brothers and one sister, are entirely dependent on an uncle who is quite unable to meet all the heavy expenses connected with maintenance and education. The boy for whom help is asked is living with his grandmother who only has the Old Age Pension and augments this by taking a lodger. Fund voted £25 towards maintenance.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

CARE OF MENTAL DEFICIENCY

THE BOARD OF CONTROL AND THE SOCIETY OF MEDICAL OFFICERS OF HEALTH

The Duties of Local Authorities

THE want of accommodation for all types of defectives was emphasised in the annual report of the Board of Control for the year 1924, and in the report for 1925 it is stated that the position has become more acute, since the number of new beds has not kept pace with the number of new cases, and nothing has been done to overtake the arrears. The Board of Control has invited local authorities to submit schemes, but the response has been poor, and the failure of local authorities to fulfil their duties is held to be hampering the beneficent objects of the Mental Deficiency Act, which was designed to give care, training, and protection to the most helpless class in the community. The total number of mental defectives ascertained up to the end of 1925 was 55,480, an increase of 6702 over the previous year. *There is strong evidence that a large* number of defectives have not yet been ascertained, some of the local authorities making insufficient use of the local branches of the Central Association for Mental Welfare in this connexion. Concerning 2338 of the cases reported by the local education authority in 1925 no action had been taken at the time of the issue of the last annual report of the Board of Control, and there were also 2141 cases otherwise ascertained for whom no form of care had yet been forthcoming. 1205 cases were "waiting removal" to an institution, being over 500 more cases than in the previous year. Only 17 local authorities have made institutional provision under Section 30 (*c*) of the Mental Deficiency Act, 7 others have acquired estates on which to establish colonies, and 18 are at least giving serious consideration to the problem.

This brief summary of the relevant section of the annual report of the Board of Control, on which we have already commented (THE LANCET, 1926, ii., 652), serves to show the magnitude of the problem and the need for examining every possible factor which may help local authorities to ascertain, classify, and place under supervision, guardianship, or institutional care the mental defectives in their districts. The various methods for dealing with mental defectives in this country are clearly summarised by Sir Robert Armstrong-Jones elsewhere in this issue of THE LANCET; it is evident that even were it possible to find suitable accommodation, guardians, or homes for every afflicted person the problem of classification would not be an easy one. But it is made more complex by the severe lack of institutional accommodation, which reacts on the selection by local authorities of cases suitable for statutory supervision or guardianship. The Board of Control have reason to believe that many local authorities have no guiding principle in the selection of suitable cases for supervision, and that large numbers are placed under supervision simply because there are no vacancies for them in institutions. As to guardianship, though the number of cases thus dealt with was 601 on Jan. 1st, 1926 (an increase of 111 on the numbers of the previous year), 54 local authorities out of a total of 121 have not a single case under guardianship, while 29 others have only one or at the most two cases.

Proposal to Appoint "Medical Officers of Mental Health"

Among the constructive suggestions made by the Board of Control is that of the appointment of whole or part-time medical officers with special training in the subject of mental deficiency to assist local committees in carrying out their work for the care, training and protection of defectives. At the present time three local authorities have appointed whole-time medical officers. In four cases general practitioners have been appointed as part-time officers, and two of these have had mental hospital or special school experience. In two other instances consultants have been appointed. The general practice, however, has been to place the medical work under the direction of the medical officer of health. Of the 333 medical officers to whom duties under the Mental Deficiency Act have been allocated by the local authorities only 108 have had special training or experience in mental deficiency work The Board of Control expresses the opinion that it is generally desirable that the medical officers actually doing the work should be in direct touch with the Statutory Committee for Mental Deficiency In their opinion efficiency is not likely to be secured if the subject is in the hands of a number of medical officers "without special training and chiefly interested in other public service" and they look forward to the time when each district will have a medical officer whose principal work is mental deficiency, and who should be the expert adviser of the committee The Board, in fact, go even further when they express conviction that "a measure which brought all mental patients under one authority both locally and centrally would be beneficial and would render a consistent and scientific treatment of the whole question possible It would then be essential that each county or county borough council should establish the post of medical officer of mental health"

Rejoinder of the Society of Medical Officers of Health.

It is hardly surprising that these suggestions have not been allowed to pass unchallenged A memorandum issued by the Society of Medical Officers of Health and appearing in the June issue of *Public Health* protests against statements in the annual report of the Board of Control which they consider to be calculated to induce local authorities to isolate mental deficiency work from the general work of public health They deprecate any suggestion that mental deficiency work should be carried out under the control of a medical officer who is not attached to the Public Health Department They point out that no proof is offered (or in their opinion exists) that those authorities which have employed whole-time medical officers exclusively for mental deficiency work have obtained better results than those who have entrusted the duties connected with this work to medical officers who combine it with other duties The Society give reasons for believing that "the chief medical adviser to the Mental Deficiency Act Committee should be the medical officer of health in whose department and under whose administrative supervision the whole of the work of mental deficiency undertaken by the county local authority should be carried out Any separation of the mental deficiency work from the Health Department must inevitably lead to increased cost and decreased efficiency. By combining various duties in one officer a substantial economy in working expenses is obtained and at the same time by allocating given proportions of time to the various duties there is no danger of any particular duty being neglected"

Such differences of opinion as to methods of dealing with the medical supervision of mental defectives at any rate point to a revival of interest in a rather depressing branch of sociology which has been unduly neglected

---

The issue of *Nature* for June 18th will include a special supplement devoted to articles on various aspects of solar eclipses, of interest not only to observers but also to general readers The publishers are Macmillan and Co, St. Martin's-street, London, W C 2, and the price is 1s

We regret to announce the death on June 8th, at a nursing home in Greenford, of Mr George Bethell, Registrar of the Medical Society of London and secretary of the Royal Medical Benevolent Fund In both these capacities Mr Bethell's work brought him into close contact with a large circle of medical men who were able to rely confidently on his ability and devotion to duty He was in his fifty-eighth year

THE LOCAL ADMINISTRATION OF MENTAL DEFICIENCY

To the Editor of THE LANCET

SIR,—Will you allow me to comment upon the memorandum recently issued by the Society of Medical Officers of Health relating to mental deficiency administration and strongly attacking what is conceived to be the attitude and policy of the Board of Control I do not propose to refer in detail to this memorandum, I would merely say that its perusal seems to indicate the existence of so much misunderstanding regarding the report of the Board of Control, its attitude towards the Board is so markedly hostile, and its language so intemperate—indeed, one might not unfairly say so offensive—that one cannot but wonder how it came to be passed by the Society This tone is all the more unfortunate since the charge may well be made that those responsible for it do not occupy an entirely disinterested position concerning the chief matter at issue

With the view that disease of mind should be regarded as part of disease in general I entirely agree The progress of psychological medicine in the past has suffered greatly from the failure to appreciate this relationship, and one of the most satisfactory features of recent years has been the gradual breaking down of the artificial barrier which has long existed between disease of mind and disease of body Further, I entirely agree that the administration of the various Acts dealing with mental disease should, so far as is possible, form part of the Public Health Service, and that there should be the closest coordination of all the branches of this service But the memorandum goes on to suggest—indeed, to claim—that this coordination can only be secured by placing the administrative control of all these services in the hands of *one individual*—namely, the medical officer of health—and it is here that I venture to demur.

My objection to this policy of the creation of the post of Pooh-Bah is based upon the deliberate opinion that, owing to the developments in medicine which have taken place in recent years, it is no longer possible for any single individual to possess that knowledge of all its branches which is necessary for efficient administration. There are certain branches—such, for example, as those dealing with venereal disease, tuberculosis, infectious diseases, inspection and treatment of school-children—an adequate knowledge of which is possessed by every well-educated medical practitioner The administration of these services may well remain in the hands of the chief medical officer, the actual work being done by special assistants But there are other branches of work in which this is not so, and this is peculiarly the case with mental disease I have no hesitation in saying that the successful ascertainment, diagnosis, treatment, and administrative disposal of persons suffering from disorder, disease, or defect of mind can only be made by a practitioner who has spent years in the study of these conditions, and that there are very few, if any, medical officers of health who possess either the special knowledge, the experience, or even the time to do this work Here also the work could doubtless be delegated to an assistant possessing the necessary qualifications, but to secure efficiency of administration it would be essential that such subordinate officer should be given a considerable degree of freedom, that his initiative should be encouraged and, most important, that he should be in personal contact with, and responsible to, the Statutory Committee of the Council charged with this duty I hold no brief for the Board of Control, but so far as I understand their attitude this is all they ask for. They appear to be of the opinion that part, at all events, of the failure of local authorities to administer the Mental Deficiency Act is due to this work having been relegated to medical officers of health who have little interest in, less special knowledge of, and still less available time to do the work The failure is unquestionable The desire of the Board that the work should be in the hands of a specially qualified officer in direct touch with the Statutory Committee does not seem unreasonable

For my part I am disposed to think that the time has come when one should go even further Psychological medicine is not only a highly specialised subject, but it is one which in the near future must inevitably lead to more and more duties being placed upon the shoulders of local administrative authorities It is a recognised fact that if work is to be well done it must be in the hands of those interested in, and having special knowledge of it, and I very much doubt whether real efficiency will be attained with regard to defectives and to the early and appropriate treatment of mental patients unless the administration of this branch of medicine is made a separate department under its own chief There are plenty of young well-qualified members of the profession taking up this special work, but they naturally hesitate to enter the service of local authorities because, so long as they so specialise, they can never attain to more than a subordinate position This is good neither for progress nor for efficient administration, nor is it in the interests of the profession generally.

It may be suggested that the creation of such a separate department would be to undo the work of coordinating the various public health services, and contrary to the aim of the Ministry of Health Act of 1919 I do not think so The aim of that Act was to secure coordination by placing administrative control in the hands of *one and the same Council*, and not in the hands of one particular official (i e, the medical officer of health), of that Council, and I see no reason why coordination should in any way suffer by the heads of the respective departments being colleagues meeting one another on equal terms Such an arrangement would certainly be more likely to attract practitioners specialising in psychological medicine, and would thereby make for greater efficiency and the advantage of the community

I am, Sir, yours faithfully,

New Cavendish st, W, June 13th A F TREDGOLD

THE EMPLOYMENT OF MARRIED WOMEN

To the Editor of THE LANCET

SIR,—I enclose a copy of a letter addressed by the Medical Women's Federation to the members of the Durham County Council, regarding the recent resolution passed by them prohibiting the employment of married women in the county service The executive committee of the Federation beg me to request you to publish this protest.

I am, Sir, yours faithfully,
VIOLET KELYNACK,
Medical Secretary, Medical Women's Federation
9, Clifford street, W, June 13th, 1927

The enclosed letter to the members of the Durham County Council is as follows —

DEAR SIRS,—The Council of the Medical Women's Federation has learned with the deepest regret that the Durham County Council has decided to debar from employment on its staff all married women, medical and otherwise, whose husbands are in the receipt of an adequate income The Medical Women's Federation has always upheld the principle that considerations affecting efficiency of work should alone govern the appointment or dismissal of medical officers, and believe that this principle is in accordance with the true interests of the community

They would venture to point out that without the enactment of special restrictions, it is always open to an appointing authority to select unmarried rather than married candidates where they consider marriage is likely to act as a handicap to their work What the new regulation will do is to keep out of sight all possible married candidates, including it may be, women of exceptional ability and experience, or in regard to whom the handicap of marriage may be comparatively slight—i e, married women without children, or where children have reached an age to make little demand on the mother's time The consideration of special cases, where the compensatory advantages may largely overbalance the possible handicap of marriage, is debarred The rule also ignores completely the undoubted fact that in medicine, and other professions also, there are branches where the personal experience gained by marriage and motherhood adds to the value of the worker, as, for instance, in baby welfare work For these reasons we feel strongly that this regulation does not tend to the maintenance of the maximum efficiency of work or to the appointment in all cases of the best qualified candidates

We quite appreciate the point of view which wishes to distribute the employment available amongst as many households as possible, where compatible with efficiency, but if economic reasons of this kind are to be taken into consideration in making appointments, they ought to be made to apply to men also who possess, for instance, private means or a wealthy wife One point that we think is often overlooked is that married medical women, at any rate, who remain in employment after marriage, are obliged to employ at least one woman to look after their households, and if they have families often two or more people who would not be employed if the mother were at home Married women, and we think this especially true of married medical women, who remain in employment after marriage, usually do so, not because of the enhanced income, but because they like their work and are peculiarly efficient at it, and they distribute often the whole of their earnings in wages and salaries to others

We trust that the Council will favourably consider this protest It is sent because we feel strongly that prohibitive regulations of this kind are grossly unfair to women who have given years of work and devotion to their profession and also to the public, who are often deprived thereby of the services of tried and skilled workers

Yours faithfully,
Christine M Murrell, President

THE SURGERY OF HERNIA

To the Editor of The Lancet

Sir,—In a letter which appeared in The Lancet on May 21st (p 1107) Dr J P. zum Busch has challenged my statement that Celsus himself operated But Leigh Watson, of Chicago, who has studied the subject of hernia most exhaustively, writes "Celsus operated extensively on umbilical hernias, &c" In the English translation of the works of Celsus, by James Grieve (1814), a detailed description of the operation of herniotomy is given (Lib vii, chap 20, page 354) It is impossible to imagine that such a fine description, including all the technical details, could be given by a mere lay writer. There is, in fact, ample internal evidence in the works of Celsus that he actually practised surgery Le Clerc, in his Histoire de la Médecine (Paris, 1760), describes the practice of Celsus in the treatment of various diseases For example, a splendid description is given of a "new method in the suture of abdominal wounds" Part II, lib iv, sect ii, chap 5, p 239) No one but an operating surgeon could have written such a fine technical account —I am, Sir, yours faithfully,

Wimpole street, W, June 13th, 1927 E M Cowell

PSYCHOGENIC ASTHMA

To the Editor of The Lancet

Sir,—In The Lancet of May 7th Dr. E B Strauss reports the cure by psychotherapy of two cases of asthma, which he regards as psychogenic Dr Strauss was unable to trace the psychogenesis to the sex instinct, whether a complete analysis would have discovered sexual factors it is impossible to say The fact is that the symptom disappeared without the patients being made conscious of sexual fixations or traumata. While the cases as reported give no evidence of the decisive importance of sexual factors, they are a striking witness to the traumatic results of actual experiences of dyspnœa—produced in the one case by a rag stuffed in the mouth by a nurse, in the other case by the water when the child fell into a stream While the theory of Freud seems insufficient to explain such reactions to dangerous stimuli, these psychogenic cases can be more clearly understood in the light of the recent development of Freudian theory by Rank, who discovered the importance of the trauma of birth in human development It is true that the average human being, in Rank's view, overcomes the painful experiences of birth and weaning, but in cases where later traumata occur, such as those in Dr Strauss's patients, the anxiety of the primal trauma can be associatively revived to cause symptoms The birth shock only becomes pathogenic in persons whose libido development has later been checked in the attempt to find substitutes for previous satisfactions lost by such experiences as painful weaning, the painful presence of rivals, or painful accidents and punishments The reaction to these traumata may be a neurotic anxiety affect or part of its physiological accompaniment such as dyspnœa —I am, Sir, yours faithfully,

San Francisco, May 19th, 1927 Cavendish Moxon

ACUTE HEPATIC ABSCESS

To the Editor of The Lancet

Sir,—The interesting account of two cases of acute hepatic abscess reported by Mr T J D Lane and Dr T A Austin in your last issue prompts me to put on record a somewhat similar case under my own care which is now doing well after operation

A lady, aged 44, had had definite symptoms of cholecystitis for at least two years Latterly her condition had become worse, her temperature rose regularly at night to 100°–101° F, her sclerotics were slightly tinged, and there was definite tenderness over the right upper abdomen She was very averse to operation and demanded X ray confirmation of gall-bladder trouble before submitting to laparotomy This was duly done by Graham's method The gall bladder showed as a very ill-defined shadow, but on one of the films a definite racemose shadow was discernable over the gall-bladder area The radiologist gave his diagnosis "cholecystitis with gall-stones present"

On opening the abdomen the first thing I noticed was a moderately enlarged and congested liver, on examining its inferior surface five small pale areas were seen bulging out, and these fluctuated to the touch. The general peritoneal cavity having been packed off the bulging areas were incised and from each of them pus oozed out. The gall-bladder was then examined, it was small in size and showed slight evidence of cholecystitis I decided to drain it through the main abdominal wound No gall stones were present. A stab wound was then made in the flank and through this a wide strip of corrugated rubber was passed to the area of the liver in which the abscesses were present

It is now four weeks since the operation and the patient has so far done well The tube came out of the gall-bladder on the tenth day and the stab wound drained a mixture of bile and pus for 15 days, when it was removed.—I am, Sir, yours faithfully,

Darlington, June 13th David R E Roberts

A POINT UNDER THE MIDWIVES ACTS

To the Editor of The Lancet

Sir,—In reference to my letter which appeared in your issue of May 28th under the above heading, the county medical officer to the Devon County Council informs me that when the Act of 1926 came into force every medical practitioner in the county was duly notified of the provision referred to in accordance with the circular of the Ministry of Health relative thereto Through the lapse of time, however, the position has arisen that some medical practitioners in the county of Devon (and doubtless in other counties) have not received any notification Bearing in mind that such documents are easily forgotten, the reasonable procedure to obviate the difficulty would be to print a notice on the forms supplied for making claims in respect of midwifery fees, indicating clearly that they must be rendered within two months of the time when the services are rendered

I am, Sir, yours faithfully,
Hugh Woods

THE LOCAL ADMINISTRATION OF MENTAL DEFICIENCY

To the Editor of THE LANCET

SIR,—Will you allow me to comment upon the memorandum recently issued by the Society of Medical Officers of Health relating to mental deficiency administration and strongly attacking what is conceived to be the attitude and policy of the Board of Control. I do not propose to refer in detail to this memorandum; I would merely say that its perusal seems to indicate the existence of so much misunderstanding regarding the report of the Board of Control; its attitude towards the Board is so markedly hostile, and its language so intemperate—indeed, one might not unfairly say so offensive—that one cannot but wonder how it came to be passed by the Society. This tone is all the more unfortunate since the charge may well be made that those responsible for it do not occupy an entirely disinterested position concerning the chief matter at issue.

With the view that disease of mind should be regarded as part of disease in general I entirely agree. The progress of psychological medicine in the past has suffered greatly from the failure to appreciate this relationship, and one of the most satisfactory features of recent years has been the gradual breaking down of the artificial barrier which has long existed between disease of mind and disease of body. Further, I entirely agree that the administration of the various Acts dealing with mental disease should, so far as is possible, form part of the Public Health Service, and that there should be the closest coordination of all the branches of this service. But the memorandum goes on to suggest—indeed, to claim—that this coordination can only be secured by placing the administrative control of all these services in the hands of *one individual*—namely, the medical officer of health—and it is here that I venture to demur.

My objection to this policy of the creation of the post of Pooh-Bah is based upon the deliberate opinion that, owing to the developments in medicine which have taken place in recent years, it is no longer possible for any single individual to possess that knowledge of all its branches which is necessary for efficient administration. There are certain branches—such, for example, as those dealing with venereal disease, tuberculosis, infectious diseases, inspection and treatment of school-children—an adequate knowledge of which is possessed by every well-educated medical practitioner. The administration of these services may well remain in the hands of the chief medical officer, the actual work being done by special assistants. But there are other branches of work in which this is not so, and this is peculiarly the case with mental disease. I have no hesitation in saying that the successful ascertainment, diagnosis, treatment, and administrative disposal of persons suffering from disorder, disease, or defect of mind can only be made by a practitioner who has spent years in the study of these conditions, and that there are very few, if any, medical officers of health who possess either the special knowledge, the experience, or even the time to do this work. Here also the work could doubtless be delegated to an assistant possessing the necessary qualifications; but to secure efficiency of administration it would be essential that such subordinate officer should be given a considerable degree of freedom, that his initiative should be encouraged and, most important, that he should be in personal contact with, and responsible to, the Statutory Committee of the Council charged with this duty. I hold no brief for the Board of Control, but so far as I understand their attitude this is all they ask for. They appear to be of the opinion that part, at all events, of the failure of local authorities to administer the Mental Deficiency Act is due to this work having been relegated to medical officers of health who have little interest in, less special knowledge of, and still less available time to do the work. The failure is unquestionable. The desire of the Board that the work should be in the hands of a specially qualified officer in direct touch with the Statutory Committee does not seem unreasonable.

For my part I am disposed to think that the time has come when one should go even further. Psychological medicine is not only a highly specialised subject, but it is one which in the near future must inevitably lead to more and more duties being placed upon the shoulders of local administrative authorities. It is a recognised fact that if work is to be well done it must be in the hands of those interested in and having special knowledge of it, and I very much doubt whether real efficiency will be attained with regard to defectives and to the early and appropriate treatment of mental patients unless the administration of this branch of medicine is made a separate department under its own chief. There are plenty of young well-qualified members of the profession taking up this special work, but they naturally hesitate to enter the service of local authorities because, so long as they so specialise, they can never attain to more than a subordinate position. This is good neither for progress nor for efficient administration, nor is it in the interests of the profession generally.

It may be suggested that the creation of such a separate department would be to undo the work of coordinating the various public health services, and contrary to the aim of the Ministry of Health Act of 1919. I do not think so. The aim of that Act was to secure coordination by placing administrative control in the hands of *one and the same Council*, and not in the hands of one particular official (i.e., the medical officer of health), of that Council, and I see no reason why coordination should in any way suffer by the heads of the respective departments being colleagues meeting one another on equal terms. Such an arrangement would certainly be more likely to attract practitioners specialising in psychological medicine, and would thereby make for greater efficiency and the advantage of the community.

I am, Sir, yours faithfully,

New Cavendish st., W., June 13th. A. F. TREDGOLD.

THE EMPLOYMENT OF MARRIED WOMEN.

To the Editor of THE LANCET

SIR,—I enclose a copy of a letter addressed by the Medical Women's Federation to the members of the Durham County Council, regarding the recent resolution passed by them prohibiting the employment of married women in the county service. The executive committee of the Federation beg me to request you to publish this protest.

I am, Sir, yours faithfully,

VIOLET KELYNACK,

Medical Secretary, Medical Women's Federation

9, Clifford street, W., June 13th, 1927.

The enclosed letter to the members of the Durham County Council is as follows:—

DEAR SIRS,—The Council of the Medical Women's Federation has learned with the deepest regret that the Durham County Council has decided to debar from employment on its staff all married women, medical and otherwise, whose husbands are in the receipt of an adequate income. The Medical Women's Federation has always upheld the principle that considerations affecting efficiency of work should alone govern the appointment or dismissal of medical officers, and believe that this principle is in accordance with the true interests of the community.

They would venture to point out that without the enactment of special restrictions, it is always open to an appointing authority to select unmarried rather than married candidates where they consider marriage is likely to act as a handicap to their work. What the new regulation will do is to keep out of sight all possible married candidates, including it may be, women of exceptional ability and experience, or in regard to whom the handicap of marriage may be comparatively slight—i.e., married women without children, or where children have reached an age to make little demand on the mother's time The consideration of special cases, where the compensatory advantages may largely overbalance the possible handicap of marriage, is debarred The rule also ignores completely the undoubted fact that in medicine, and other professions also, there are branches where the personal experience gained by marriage and motherhood adds to the value of the worker, as, for instance, in baby welfare work For these reasons we feel strongly that this regulation does not tend to the maintenance of the maximum efficiency of work or to the appointment in all cases of the best qualified candidates

We quite appreciate the point of view which wishes to distribute the employment available amongst as many households as possible, where compatible with efficiency, but if economic reasons of this kind are to be taken into consideration in making appointments, they ought to be made to apply to men also who possess, for instance, private means or a wealthy wife One point that we think is often overlooked is that married medical women, at any rate, who remain in employment after marriage, are obliged to employ at least one woman to look after their households, and if they have families often two or more people who would not be employed if the mother were at home Married women, and we think this especially true of married medical women, who remain in employment after marriage, usually do so, not because of the enhanced income, but because they like their work and are peculiarly efficient at it, and they distribute often the whole of their earnings in wages and salaries to others

We trust that the Council will favourably consider this protest. It is sent because we feel strongly that prohibitive regulations of this kind are grossly unfair to women who have given years of work and devotion to their profession and also to the public, who are often deprived thereby of the services of tried and skilled workers

THE SURGERY OF HERNIA

To the Editor of The Lancet

Sir,—In a letter which appeared in The Lancet on May 21st (p 1107) Dr J P zum Busch has challenged my statement that Celsus himself operated But Leigh Watson, of Chicago, who has studied the subject of hernia most exhaustively, writes "Celsus operated extensively on umbilical hernias, &c" In the English translation of the works of Celsus, by James Grieve (1814), a detailed description of the operation of herniotomy is given (Lib vii , chap 20, page 354) It is impossible to imagine that such a fine description, including all the technical details, could be given by a mere lay writer There is, in fact, ample internal evidence in the works of Celsus that he actually practised surgery. Le Clerc, in his Histoire de la Médecine (Paris, 1760), describes the practice of Celsus in the treatment of various diseases For example, a splendid description is given of a "new method in the suture of abdominal wounds" Part II, lib iv, sect ii, chap 5, p 239) No one but an operating surgeon could have written such a fine technical account —I am, Sir, yours faithfully,

Wimpole street, W , June 13th, 1927 E M Cowell

PSYCHOGENIC ASTHMA

To the Editor of The Lancet

Sir,—In The Lancet of May 7th Dr E B Strauss reports the cure by psychotherapy of two cases of asthma, which he regards as psychogenic Dr Strauss was unable to trace the psychogenesis to the sex instinct, whether a complete analysis would have discovered sexual factors it is impossible to say The fact is that the symptom disappeared without the patients being made conscious of sexual fixations or traumata While the cases as reported give no evidence of the decisive importance of sexual factors, they are a striking witness to the traumatic results of actual experiences of dyspnœa—produced in the one case by a rag stuffed in the mouth by a nurse, in the other case by the water when the child fell into a stream While the theory of Freud seems insufficient to explain such reactions to dangerous stimuli, these psychogenic cases can be more clearly understood in the light of the recent development of Freudian theory by Rank, who discovered the importance of the trauma of birth in human development It is true that the average human being, in Rank's view, overcomes the painful experiences of birth and weaning , but in cases where later traumata occur, such as those in Dr Strauss's patients, the anxiety of the primal trauma can be associatively revived to cause symptoms The birth shock only becomes pathogenic in persons whose libido development has later been checked in the attempt to find substitutes for previous satisfactions lost by such experiences as painful weaning, the painful presence of rivals, or painful accidents and punishments The reaction to these traumata may be a neurotic anxiety affect or part of its physiological accompaniment such as dyspnœa —I am, Sir, yours faithfully,

San Francisco, May 19th, 1927 Cavendish Moxon

ACUTE HEPATIC ABSCESS

To the Editor of The Lancet

Sir,—The interesting account of two cases of acute hepatic abscess reported by Mr T J D Lane and Dr T A Austin in your last issue prompts me to put on record a somewhat similar case under my own care which is now doing well after operation

A lady, aged 44, had had definite symptoms of cholecystitis for at least two years Latterly her condition had become worse, her temperature rose regularly at night to 100°–101° F , her sclerotics were slightly tinged, and there was definite tenderness over the right upper abdomen She was very averse to operation and demanded X ray confirmation of gall-bladder trouble before submitting to laparotomy This was duly done by Graham's method The gall bladder showed as a very ill-defined shadow, but on one of the films a definite racemose shadow was discernable over the gall-bladder area The radiologist gave his diagnosis "cholecystitis with gall-stones present"

On opening the abdomen the first thing I noticed was a moderately enlarged and congested liver , on examining its inferior surface five small pale areas were seen bulging out, and these fluctuated to the touch The general peritoneal cavity having been packed off the bulging areas were incised and from each of them pus oozed out. The gall-bladder was then examined , it was small in size and showed slight evidence of cholecystitis I decided to drain it through the main abdominal wound No gall stones were present A stab wound was then made in the flank and through this a wide strip of corrugated rubber was passed to the area of the liver in which the abscesses were present

It is now four weeks since the operation and the patient has so far done well The tube came out of the gall-bladder on the tenth day and the stab wound drained a mixture of bile and pus for 15 days, when it was removed —I am, Sir, yours faithfully,

Darlington, June 13th David R E Roberts

A POINT UNDER THE MIDWIVES ACTS

To the Editor of The Lancet

Sir,—In reference to my letter which appeared in your issue of May 28th under the above heading, the county medical officer to the Devon County Council informs me that when the Act of 1926 came into force every medical practitioner in the county was duly notified of the provision referred to in accordance with the circular of the Ministry of Health relative thereto Through the lapse of time, however, the position has arisen that some medical practitioners in the county of Devon (and doubtless in other counties) have not received any notification Bearing in mind that such documents are easily forgotten, the reasonable procedure to obviate the difficulty would be to print a notice on the forms supplied for making claims in respect of midwifery fees, indicating clearly that they must be rendered within two months of the time when the services are rendered

I am, Sir, yours faithfully,
Hugh Woods
London and Counties Medical Protection Society, Ltd ,
Victory House, Leicester square, W C , June 9th

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND —At an ordinary meeting of the Council held on June 9th, with Sir Berkeley Moynihan, the President, in the chair, the following examiners were elected for the undermentioned examinations —

Primary Fellowship (Physiology) —Prof R J S McDowall and Prof C A Lovatt Evans
Second Conjoint (Physiology) —Dr D H de Souza
Final Conjoint (Midwifery) —Dr T B Davies
Diploma in Public Health (Part II) —Dr C W Hutt
Diploma in Ophthalmic Medicine and Surgery (Part II) —Mr Reginald A Greeves
Diploma in Laryngology and Otology (Part I) —Mr W Mayhew Mollison

Sir Berkeley Moynihan was re-elected as representative of the College on the Court of Governors of Sheffield University for three years —A vote of thanks was given to Miss Hunter, of Blackheath, for presenting to the College a combined bookcase and writing-table, formerly the property of John Hunter —The thanks of the Council were expressed to Sir John Bland-Sutton, on his retirement, for his services during his term of office on the Council extending over 17 years, including three years as President

As the result of the recent Final Fellowship Examination, held from May 19th to June 3rd, for which 108 candidates presented themselves, 25 candidates (24 men and 1 woman) were approved One candidate, Harry I Deitch (Middlesex Hospital) although successful, is not entitled to the diploma until he has attained the requisite age The Council accordingly conferred the diploma of Fellow upon the following 24 candidates who have complied with the necessary by-laws —

H G Armstrong, Toronto , Alfreda H Baker, Belfast , H B Bullen Cambridge and St Bart 's W K Connell, Glasgow and London , W H A Dodd Liverpool and Guy's , R L Dodds and I J Fraser, Belfast , W H Gervis, Cambridge and St Thomas's , C M Gwillim St Bart 's and St George's , W J Henry Toronto and London , R Y Hudson, Middlesex , D McKelvey, Edinburgh and Guy's , W A Mill, Guy's J D R Murray, Cambridge and Middlesex , M A Paul, Ceylon and King's Coll G H Pitt, Guy's , W A Richards, Charing Cross E W Riches and E L Robert, Middlesex , J Roberts Liverpool and London , F W Roques, Cambridge and Middlesex , S Y Unsworth, Liverpool A L Walker, Cambridge and Middlesex , and E Wolff, Univ Coll

The diploma of M R C S was also conferred upon the following candidates who have passed the requisite examinations and have now complied with the by-laws —

Y F Anderson, Westminster F A J Bouloux Univ Coll Ethel E M Ogilvie, Dulcie J Peake, Winifred M Turner, and John B Walker, Royal Free

UNIVERSITY OF BRISTOL —At recent examinations the following candidates completed the undermentioned examinations —

FINAL EXAMINATION FOR M B , CH B

Part I —G D J Ball O J P Bollon T L Cleave, R D Jenkins, Helen B Murgoci, Ethel M Redman, and Phœbe C Vine
Part II —Helen M Aldwinckle J C Batt H E C Bentley, E C Bernard, G L Feneley, Ernest May, E S Rogers, J R E Sansom, and Maiprom Srisvasti

FINAL EXAMINATION FOR DENTAL DIPLOMA

H G Clapp, E J Tanner, G W Vowles

ROCKEFELLER MEDICAL FELLOWSHIPS — The Medical Research Council announce that on behalf of the Rockefeller Foundation they have made the following awards of Medical Fellowships provided by the Foundation and tenable in the United States of America during the academic year 1927–28 These Fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and who are likely to profit by a period of work at a university or other chosen centre in America before taking up positions for higher teaching or research in the British Isles —

Robert William FitzGerald Collis M B Camb , M R C P Lond (resident medical officer King's College Hospital London)

David Krestin M D , M R C P Lond (medical registrar, London Hospital)

Geoffrey Lewis Peskett, M A Oxf (demonstrator in biochemistry, University of Oxford)

Isabella McDougall Robertson M D Lond (research worker in the pathological laboratory Maudsley Hospital London)

*Thomas Tennent, M B Glasg (assistant medical officer Maudsley Hospital)

Edgar William Todd, M D Camb (research worker in the inoculation department St Mary's Hospital)

* Dr Tennent has been appointed on modified conditions while holding a scholarship from another source

UNIVERSITY OF DUBLIN —It is proposed to confer honorary degrees on June 28th upon Sir Humphry Rolleston, of Cambridge, and Prof Harvey Cushing, of Harvard

Trinity College School of Physic —The Fund subscribed by the medical graduates of the University to commemorate the bicentenary of the foundation of the School of Physic has now been handed to the Board of Trinity College, for the purpose of establishing a bicentenary memorial prize to be awarded each year to the winner of the medical or surgical travelling prize In accepting the Fund the Board has expressed thanks to the subscribers for " a very generous benefaction to the College " The amount of the Fund is about £730

CANCER RESEARCH IN DUBLIN —The Committee of the National Cancer Campaign (Ireland) has decided to hold its first public meeting to ask for public support on June 27th. The meeting will be held in the Royal College of Surgeons, and the chair will be taken by the Marquis of Dufferin and Ava, while among the speakers will be Sir Humphry Rolleston and Prof Harvey Cushing

GLASGOW UNIVERSITY CLUB, LONDON —The annual summer dinner of this club will be held at the Trocadero Restaurant, Piccadilly, W 1, on Friday, July 1st, Dr Charles O Hawthorne in the chair Any Glasgow University men who, though not members of the club, desire to attend, are requested to communicate with the honorary secretaries, at 62, Harley House, London, N W 1

ST JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY — The annual oration of this society (which incorporates the London Dermatological Society) will be delivered at 5 P M. on Wednesday, June 22nd, at St John's Hospital, Leicester-square, by Dr H Haxthausen, of Copenhagen His subject will be Streptococcic Pityriasis The oration will be followed by the annual general meeting

THE LATE DR A E NORMINGTON —On May 27th, at the age of 55, Dr Arthur Edward Normington died at Rhos-on-Sea, where he had been living in retirement since the early part of this year He was born at Keighley, and educated first at the local grammar school and later at Owens College, graduating in medicine with honours at the Victoria University of Manchester in 1896 In the same year he won the medical and surgical clinical prize at the Royal Infirmary, Manchester, and after qualification he was appointed prosector and assistant demonstrator of anatomy at Owens College A short period was then spent as resident medical officer at Stoke Union Hospital, after which, about 27 years ago, he settled in practice at Nelson, Lancashire At first he acted as assistant to Dr W E Little, whose practice he later took over Dr Normington took a keen interest in ambulance work, and during the war was commandant of Reedyford Auxiliary Military Hospital, which later, largely as a result of his efforts, was turned into a memorial hospital for the use of the town. He was appointed a Member of the Order of the British Empire in recognition of his war services, and in 1920 was made a magistrate He leaves a widow, two sons, and one daughter

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Monday, June 20th, at 2 30 P M., Dr A J Whiting will give a medical clinical demonstration at the Prince of Wales's Hospital , on Wednesday, June 22nd, at 4 P M., Mr C A Joll will give a surgical demonstration at the Royal Free Hospital on the Surgical Treatment of Goitre , on Friday, June 24th, at 3 P M., Mr Griffith will give a clinical ophthalmic demonstration at the Royal Eye Hospital These demonstrations will be free to members of the medical profession On June 27th a fortnight's course will begin at the City of London Hospital for Diseases of the Heart and Lungs (Fee £2 2*s*) In July five special courses will be given in various subjects The first will be an all-day course from July 4th to 16th at the National Hospital for Diseases of the Heart The daily sessions will begin at 10 A M and last until 4 P M , the numbers are strictly limited to 20 On July 11th the Prince of Wales's Hospital group will start a fortnight's course in general medicine, surgery, and the specialties, from 10 30 A M to 5 30 P M daily On the same date a week's course will begin at the St Mark's Hospital for Diseases of the Rectum, occupying six afternoons and three mornings The other two courses taking place in July are part-time courses —viz , a month's course in neurology at the West End Hospital for Nervous Diseases, starting on July 4th and consisting of lecture-demonstrations at 5 P M daily , and a course in infectious fevers at the Park Hospital, on Wednesdays at 2 30 P M , and Saturdays at 11 A.M , from July 13th to 30th A general course of work for which a separate programme is issued, is also provided by the Fellowship at the associated hospitals Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole street, London, W 1

THE death is announced on June 11th of Dr Alexander Hugh Freeland Barbour who was at one time President of the Royal College of Physicians of Edinburgh and was physician to the gynæcological department of Edinburgh Royal Infirmary

MEDICO-LEGAL SOCIETY —The annual general meeting of this society will be held at 11 Chandos-st, London, W., on Thursday June 23rd, at 8 30 P M At the conclusion of business Lord Riddell will read a paper on the Law and Ethics of Medical Confidences. A discussion will follow

RESEARCH DEFENCE SOCIETY —The annual general meeting will be held at the house of the Medical Society of London, 11, Chandos-street Cavendish-square, W 1, on Tuesday June 21st, at 3 P.M., when Lord Lamington will take the chair Prof. Julian Huxley will give the first Stephen Paget Memorial Lecture, his subject being Research and the Community.

ST BARTHOLOMEW'S HOSPITAL —Sir Berkeley Moynihan, President of the Royal College of Surgeons of England has accepted an invitation to take charge of the work of the Surgical Professorial Unit at St Bartholomew's Hospital and Medical College from June 15th to 30th On previous occasions Prof Harvey Cushing, of Harvard University and Prof Hugh Cabot, of Ann Arbor University, have accepted similar invitations to the hospital.

KING'S COLLEGE MEDICAL SOCIETY.—A Lister Memorial Lecture will be delivered at Kings College, Strand, London by Sir StClair Thomson, on Thursday June 23rd at 5 P M The chairman will be Sir Arthur Keith F R S The lecture is primarily intended for the medical students of London who were unable to attend the official celebrations held during the Easter vacation At 4.30 P.M. a wreath will be placed on the memorial tablet outside the chapel by the President of the Medical Society

LIVINGSTONE COLLEGE —On June 10th Commemoration Day was celebrated at the College The Chairman was Sir John Rose Bradford President of the Royal College of Physicians who spoke of the recent great advance in the work of hospitals, in the technique of medicine, in the recognition and treatment of disease, and further still in the work of nurses and almoners, who had to receive some medical training before they could carry out their duties efficiently This showed that the attitude of the medical profession to those outside it had altered somewhat of late there was not the same feeling of mystery over the profession as in former days, and it was recognised that the problems of medicine were so urgent and difficult and complex that all the aid was required that could possibly be got While expert professional knowledge was essential as regards the treatment of disease, it was very necessary that there should be knowledge of lesser degree, and medicine owed a lot to such people as missionaries who without any expert knowledge of medicine had yet thanks to the training that they had received at such colleges as Livingstone College rendered a great service to medicine. A little knowledge was capable of being of great service. He had been much impressed by the reports he had read from students of the College in all parts of the world As missionaries they were often in situations where medical aid could not be got, and the training they had received was of immense value not only in treating but in preventing disease.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY —The annual general meeting was held at Victory House Leicester-square London, W on June 8th Sir John Rose Bradford the President, being in the chair In proposing that the annual report and statement of accounts should be adopted, the President called attention to the increase in the work of the Society and the gravity of some of the cases which they had had to defend The membership of the Society had increased considerably, being now in the region of 10 000 Even now the membership of this Society and its sister society did not account for more than about 50 per cent. of the medical profession of the country That those who did not join a defence society ran very great risks was exemplified in one or two recent cases The President emphasised the importance of members in any difficulty coming first to the Society before taking any action and of making full use of X ray examination in the treatment of fractures The President referred to the large accumulated fund recorded in the financial statement, which fund made it possible to conduct to a successful issue very expensive cases Dr C M Fegen, in proposing the re-election of Sir John Rose Bradford as President referred to his untiring efforts on behalf of the Society Mr P Sidney Spokes seconded the motion which was carried unanimously as was also a motion for the re-election of Vice-Presidents, members of council and other officers a special vote of thanks being given to the Society's solicitors, Messrs Le Brasseur and Oakley

Parliamentary Intelligence.

HOUSE OF COMMONS.

MONDAY JUNE 13TH

Exchequer Grants to Voluntary Hospitals

Mr LUNN asked the Minister of Health the total amount allocated from the Exchequer in aid of voluntary hospitals since 1918 and whether the Voluntary Hospitals Commission was still in existence and had the power to give further financial assistance, and to what extent —Sir KINGSLEY WOOD replied . Excluding contributions towards specific grant-aided services, the total Exchequer grants in aid of the general expenses of voluntary hospitals since 1918 have amounted to £500 000 voted by Parliament on the recommendation of Lord Cave s Committee. The voluntary Hospitals Commission is still in existence, but it has no funds at its disposal

Amendment of Law of National Health Insurance

Captain FRASER asked the Minister of Health if, in view of the fact that ex-Service men who were new entrant voluntary contributors under the Widows', Orphans', and Old Age Contributory Pensions Act 1925 must be regarded as subject to a reduction of sickness and disablement benefit while in receipt of a 100 per cent pension or allowances unless they had satisfied the requalification conditions of Section 60 (1) Provision (1) and (2), of the National Health Insurance Act of 1924 during their previous period of insurance he would undertake that an amendment of the law would be made forthwith in order to relieve approved societies of the penalties arising from over-payment which they had in good faith already made —Sir KINGSLEY WOOD replied It is intended to include in the amending Health Insurance Bill arising out of the report of the Royal Commission provision to meet the difficulty to which the hon and gallant Member calls attention

TUESDAY JUNE 14TH

Poor-law Relief

Mr LUNN asked the Minister of Health the number of able-bodied men and women in receipt of Poor-law relief in the months of January February March and April, 1926 and 1927 —Mr CHAMBERLAIN replied · Figures based on a classification distinguishing "able-bodied" persons are not now obtained The average numbers of males over 16 years of age ordinarily engaged in some regular occupation and the average numbers of females over 16 years of age who were ordinarily so engaged or were the dependent wives of men ordinarily so engaged who were in receipt of domiciliary Poor-law relief in England and Wales during the months of January, February, March and April, 1926 and 1927 were as follows —

Average Numbers

	1926		*1927*	
	Males	*Females*	*Males*	*Females*
January	150 448	135 953	177 054	153 800
February	149,648	133,914	159 451	137 201
March	145,691	129,786	150,644	129 255
April	142,048	125,775	141,311	121,874

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED

JUNE 4TH 1927.

Notifications —The following cases of infectious disease were notified during the week —Small-pox. 254 (last week 266) , scarlet fever 1671 · diphtheria. 792 ; enteric fever, 59 ; pneumonia 1036 . puerperal fever, 36 puerperal pyrexia 102 cerebro-spinal fever, 11 acute poliomyelitis 1 acute polio-encephalitis 3 encephalitis lethargica 28 ; continued fever 2 dysentery 6 ophthalmia neonatorum 125

Cases of small-pox were notified from the counties of Derby 4 Durham 150 Lancaster 7, Northumberland 6 Yorks North Riding 2, West Riding 48 Monmouth 37 None was reported from London Kent, Middlesex, Nottingham, Stafford, Surrey, or Glamorgan.

Deaths —In the aggregate of great towns including London there were no deaths from small-pox 1 (0) from enteric fever 35 (1) from measles 5 (1) from scarlet fever 30 (7) from whooping-cough 26 (9) from diphtheria 49 (10) from diarrhœa and enteritis under two years and 12 (7) from influenza The figures in parentheses are those for London itself

Notes, Comments, and Abstracts.

THE CARE OF THE MENTALLY DEFECTIVE *

By Sir Robert Armstrong-Jones, C B E , M D , F R C P Lond ,
LORD CHANCELLOR'S VISITOR IN LUNACY

There are certainly over 150,000 weak-minded persons at the present moment in England and Wales who need protection and care on account of their mental and physical infirmity Technically, they are described as aments They are all suffering from disease, a structural and organic defect of the brain, and are unlikely to be permanently cured Of this number, 55,000 are admittedly in need of supervision, whilst only about 1 in 3—i e , about 21,000, or, roughly, 1 in 8 of the total number—are actually under recognised control These are being cared for in institutions of six kinds, which are in existence under the Mental Deficiency Act, 1913 The available accommodation may be classified as follows —

1 *State institutions*, managed entirely by the Board of Control —One at Rampton, near Nottingham, cares for about 500 of the most incorrigible, unmanageable, and wrongdoers of the mentally defective class These are of all ages, they are unfit to be at large, and most of them must need permanent protection Another institution is the one at Warwick for 50 girls These are taught useful work, and are mainly trained for domestic service They live together in a hostel, and their surroundings are made to correspond as much as possible with those of normal people Some of them go to work in the neighbourhood, but live in the hostel Their employers are fully informed of their infirmities before they are engaged, so that they may adapt themselves as far as can be to meet their defects So successful is the training here that many of the patients obtain permanent situations, and the girls are happy, for they are encouraged to feel there is some hope for them, and that there is something to work for , in consequence there is a good feeling, good order and method, and there is no resentment against those who are placed in charge

2 *The certified institutions* (certified by the Board of Control) include Royal Earlswood Institution, Royal Albert, at Lancaster, and Royal Eastern Counties, at Colchester There are altogether 76 in the country , 23 of them are provided by local authorities, and the remaining 53 by philanthropic bodies and private munificence Altogether they provide about 13,000 beds

3 *Certified houses*—These are owned and managed by private persons for profit, and are certified for the reception of defectives by the Board of Control They are of the status of our private asylums and licensed houses for the insane, and they receive about 300 patients, all of whom pay for their maintenance

4 *Approved homes* provide accommodation for about 400 The patients are either supported by relatives and friends, or are paid for by local authorities, such as boards of guardians The homes are approved by the Board of Control

5 *Poor-law institutions*—Under Section 37 of the Act, the Poor-law institutions throughout the country may receive mental defectives, and there are about 6000 cases so housed. About one-third of them are in the Metropolitan Asylums Board's certified institutions in London. All the institutions mentioned are inspected by the Board of Control

6 Lastly, there are cases under *guardianship* and those in *private care* At the present time throughout England and Wales there are about 800 mental defectives under guardianship , among them there are nearly twice as many girls and women as there are boys and men These cases are placed out under suitable conditions of care, control, and training It has always been possible, where cases prove unsuited to these conditions, to transfer them back to institutions , but by an Amendment Act, 1925, it is now possible to transfer cases from institutions to guardianship—a great improvement It is strongly urged, however, that before such a transfer is made, patients should be discharged from the institution for six months' trial on "licence," as it is called This enables them to go into a family and to return if necessary, without the trouble of securing the "varying order," if the trial on guardianship is not a success It is the local authority that must—if necessary—apply for the varying order to the judicial authority, and with the parents' consent. The paramount difficulty in guardianship is to find suitable guardians ; the parents are sometimes very unsuitable

Control and Education

As is well known, all registered mental cases are under legal control The Lunacy Act, 1890 and since, deals with the insane, sometimes referred to as dements For their control a medical certificate is required (two for private patients) and a justice's order The Mental Deficiency Act, 1913, deals with persons who are mentally defective "from birth or from an early age," described as aments In their case, also, two medical certificates are required, together with a petition and an order

The local education authority is bound by statute to provide free education for all children, including mentally defective children, by the Act of 1899, special schools being provided if necessary The age for defectives is from 7 to 16 It is further the duty of the education authority to notify the local authority when certain mental defectives need subsequent supervision—i e , when they are suitable for guardianship Voluntary associations have undertaken the task of supervision in the case of nearly 16,000 children, which shows the immense amount of voluntary work done for this class, whilst 15,000 cases are statutory supervision cases, being visited in their own homes by paid officers, as well as by voluntary social workers Another duty which is imposed by statute upon the local authority is described as ascertainment, they have to find out the number and names of mental defectives in their districts Seventy-one local authorities, however, have appointed no special officers to do this work, although there is a statutory committee in each district It is often difficult to bring these cases under the Act, unless they are being neglected, and to prove neglect is not easy even when one or both of the parents is mentally defective

A third duty of local authorities is to provide "suitable and sufficient" accommodation for all mental defectives who are certified, or are ordered to be sent into institutions At present this is utterly inadequate, as only 17 out of a possible 124 local authorities have so acted, and only 5000 beds have been provided Because the amount of accommodation is so small, it is impossible to secure a proper classification of the cases, which is of paramount importance in training and treatment So inadequate was the accommodation provided, that the Minister of Health, as far back as three years ago, urged the various local authorities (through the Board of Control) to reconsider their legal responsibility, and to submit various schemes for housing, training, and protecting the members of this class, as only accommodation for about 1 in 8 was then arranged for

Again, not only is ascertainment a statutory obligation, but supervision and guardianship are also necessary Yet inquiry shows that only 53 local authorities out of 124 in England and Wales have appointed their own special officers for this work, the others delegate their responsibility to voluntary associations or to health officers, relieving officers, welfare workers, district nurses, and school attendance officers In some instances the secretary of the voluntary association has the duty of ascertainment, supervision, and guardianship, and it is a heavy task even when the official is highly trained, because the necessary information for treatment has to be obtained from many different sources It has to be got not only from the education authority, but also from the police-courts, from probation officers, and even from the local asylums, apart from what is derived from boards of guardians or medical officers of health Although 55,000 cases need care, accommodation is provided for 1 in 3 of these.

All weak-minded persons need protection, care, and control, not only on account of inability and incapacity to maintain an independent existence themselves, but also because, when neglected, they become a danger to the community, committing crimes, spreading disease, and often propagating their inherited deficiencies

Epidemic Encephalitis and Its Results

The reappearance of an old disease, described in the sixteenth century and now known as epidemic encephalitis, has given the community much anxious thought owing to its permanently disabling effects on the bodies and minds of its victims The disease is fatal to 50 per cent. of those attacked, and most of those who survive are never the same again , about 200 of these are already in asylums, 100 more are in mental deficiency institutions, and many are wrecks and derelicts cared for in our workhouse infirmaries Two-thirds of them are juveniles, and many of them commit anti-social acts and are to be seen in the juvenile courts It is only recently, however, that any public authorities have provided special places for them, and only London and Lancashire have done this There are 100 beds at Winchmore Hill, in the north of London, and there are 30 at West Park Asylum, Epsom, where the subjects of this disease are studied and where school classes, exercise games, and suitable occupation is provided The great difficulty has been to bring these cases under the provisions of the Act of 1913, as the disease is not "from an early age or from

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Great Hasceley, Oxfordshire, and Filey, York, E R.

Births, Marriages, and Deaths.

BIRTHS.

Crook —On June 5th, at South Eaton place, London, S W, the wife of Eric A Crook, F R C S, of a daughter

Davidson —On June 6th, at a nursing home, Bournemouth, the wife of A Whyte Davidson, M B, F R C S Edin, of a son

Miller —At Streatham Manor Nursing Home on June 9th, to Emily, wife of R S Miller, M D, of Cairo—a son

DEATHS

Barbour —On June 11th, at Charlotte-square, Edinburgh, suddenly, Alexander Hugh Freeland Barbour, M D, LL D, of Gryffe, Bridge of Weir

Liston —On June 11th, at a nursing home in London, following an operation, Walter Lawrence Liston, M D, of Hereford House Tewkesbury, aged 58

North —On June 6th, at Worthing, Edward North, C B, Colonel, A M S (retd), aged 70

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

---

National Association for the Prevention of Tuberculosis —The thirteenth annual conference of this Association will be held in the Great Hall, British Medical Association House, Tavistock-square, London, W C 1, on Thursday, Friday, and Saturday, June 30th to July 2nd It will be open to all persons interested in tuberculosis on payment of the fee of one guinea Mr Neville Chamberlain, Minister of Health, will open the Congress at 10 30 A M. on June 30th, after which Sir John Robertson will give an address on Present Lines of Attack on Tuberculosis their Relative Value A discussion on Housing Home Conditions, will follow On July 1st there will be a discussion on Housing Industrial Conditions Visits have been arranged to various places in the neighbourhood of London

Macewen Memorial Lecture

ON THE

MENINGIOMAS ARISING FROM THE OLFACTORY GROOVE AND THEIR REMOVAL BY THE AID OF ELECTRO-SURGERY.*

Delivered in the University of Glasgow on June 21st, 1927,

BY HARVEY CUSHING, C B , F R C S ENG ,
PROFESSOR OF SURGERY IN HARVARD UNIVERSITY

To know before operating, not only *where* a growth is to be found but *what* its nature will be, must be one's aim if he is successfully and intelligently to deal with an intracranial tumour of any kind Forewarned is to be forearmed, and nothing may be more disconcerting in this particularly difficult sort of surgery than, when ill-prepared, to turn down possibly an insufficiently large bone-flap and to stumble unawares upon a large vascular meningioma What was looked forward to as a simple procedure may suddenly be transformed into one of magnitude and exceptional gravity And by ill-prepared I mean without the precaution of having raw muscle at hand for implantation ; of having the patient's blood grouped, a donor selected, and a separate team prepared to give a transfusion , and possibly, too, of having at hand the electro-surgical adjunct to which I particularly wish to call attention in this Macewen Lecture . .

There is, perhaps, a special justification in the selection of this topic for consideration here in Glasgow as a compliment not only to Macewen, whose early operation for a frontal meningioma has been referred to, but out of deference as well to his colleague John Cleland What is more, if one may correctly interpret an account of an operation for a " tumour of the hypophysis " as described by Macewen, he had actually encountered and removed, in part at least, one of these very lesions in question [1]

In an address [2] given a few years ago in which the meningeal tumours were dealt with from a general point of view, I had the satisfaction of pointing out that Prof Cleland had probably been the first to make clear that *they originate from the cells of the pia arachnoid rather than from the dura as commonly supposed* [3] One of the tumours which he had studied had been found while dissecting the body of a female said to have been 50 years old, who for many years had been an epileptic with impaired mental faculties and who had finally died of bronchitis Cleland's sketch of the lesion (Fig 1) shows a symmetrically placed olfactory-groove meningioma of moderate size, of which he gave the following excellent description .—

> The tumour was seen upon more careful examination to be closely adherent to the crista galli and cribriform plate of the ethmoid It was deeply cleft in front by the falx cerebri, which, however, was quite free from it, nearly to its base Near its base it was attached to the dura mater by delicate tissue, quite distinct from the proper texture of the membrane, and which was easily divided with a needle. In this way it could be detached from the dura mater as far as the orifices of the larger perforations in the mesial border of the cribriform plate with the processes of dura mater lining which it appeared to be closely connected By its bulk it had pressed not only on the brain, but to a slight extent on the left orbital wing of the sphenoid The surface was nodulated, and partly smooth, partly papillary and villous The villosities when pressed asunder easily allowed deep cracks to open between them. .
>
> When a transverse vertical section had been made, the cut surface exhibited a uniform appearance similar in colour to the grey matter of the brain The centre of the section passed through a small irregular plate of bone about a couple of lines deep and twice as long, placed vertically in the mesial line, about half an inch above the crista galli and slightly connected with the falx in front It presented the lacunæ and canaliculi of true bone, and was exactly similar to the ossification frequently met with in the edge of the falx
>
> Small portions of the tumour, prepared for microscopic inspection, when slightly rubbed against the glass cover, allowed a large quantity of granular matter to separate from them rendering opaque the fluid in which they were A large bulk of the tumour consisted of such matter, which was composed in great part, if not entirely, of nucleated cells, of which numbers were seen about 1–3000th of an inch in diameter But the most remarkable elements of the tumour were of a concretionary character, partly based on the cellular, partly on the fibrous element. The cellular concretions were round structures, strongly refracting *light, and capable of being cracked by pressure of the glass cover* The largest of them were about 1-200th of an inch in diameter, and much resembled the corpora amylacea found in brain substance, or spherical prostatic concretions

This particular tumour Cleland called a " villous tumour of the arachnoid," and he conceived that it *perhaps originated from the pacchionian corpuscles* But he was not the first to picture one of these lesions ; Cruveilhier 30 years before had given in his celebrated atlas [4] an excellent illustration (Fig 2) of a similar case Tumours of this sort unexpectedly encountered in a post-mortem examination have naturally aroused interest and the specimens are apt to find their way into pathological museums There is a typical example labelled psammoma, in the Charcot Museum at the Salpêtrière (Spec D III 16), and in the Museum of the Royal College of Surgeons in London may be seen (No 1452 1) a small tumour which serves to indicate, better than do the larger ones their characteristic point of origin (Fig 3) Virchow, in his classical work on tumours,[5] describes and pictures just such a case, the small, cherry-sized growth having been situated " close behind the crista galli and the attachment of the falx in the median line "

My first personal experience with one of these olfactory-groove tumours was 16 years ago , and during the life of the patient I had no preconception of what the lesion would prove to be The tumour had advanced to such a stage that there was complete blindness, mental deterioration, and distressing headaches There were also unmistakable evidences of pituitary insufficiency, with a sella turcica shown by the X ray to be largely destroyed A subtemporal decompression was performed without avail and the poor man not long afterwards was released by death from his troubles

Owing to my special interest at the time in pituitary disorders the case happened to be reported [6] as an example of hypopituitarism secondary to an adjacent tumour The photographs (Figs 4–6) show that the lesion had attained a large size ; had spread backwards so as to overlie and compress the pituitary body ; had extended into the ethmoid cells ; and what the photograph does not show, had forced its way without invading the brain into every crack and cranny of the neighbourhood even down into the sheaths of Schwalbe almost as far as the eyeball One of these tumours in this terminal stage is, of course, hopelessly inoperable, and in 1911 when this case was observed, I little expected ever to see another example birth," and Mr Compton Wood, M P, has brought in a Bill, acceptable to all parties to enable cases of this kind, who must be kept a long time under supervision, to be properly cared for

---

* The first portion of this lecture (here omitted) was devoted primarily to a consideration of the traditions of the Glasgow School of Surgery, and secondarily to a description of certain of the hitherto inoperable meningiomas arising from the floor of the anterior cranial chamber

Conclusion

Even from the standpoint of economy alone, it is most desirable that the whole class of the enfeebled in mind and body should receive care and protection, as well as supervision It is a waste of public money for these weak-minded persons to be cared for expensively until the age of 16 and then to be thrown upon the world, when it is left to the thrifty and the prudent to support them—and often their children—either in prisons as delinquents, or as patients in hospitals and asylums Yet this burden can be relieved by taking action Among the measures suggested are the provision of occupation centres, frequent visiting and supervision of defectives, and the prevention of their marriage I think the question of sterilisation may be disregarded Some authorities advise as the only solution the provision of special colonies with cottage homes and workshops for cases from the age of 1 upwards

PLAGUE PREVENTION AND THE FUMIGATION OF SHIPS

THE United States Quarantine Regulations require that ships entering their ports shall be fumigated every six months but [1] it became known last year that many ships in which there were no rats were being compulsorily disinfected in compliance with regulation Fumigation being not only an expense to the shipowner but a restraint to trade, the Public Health Service determined to inquire whether in some or all ships the six months period might be safely extended provided that inspection of the ship could be shown to furnish a trustworthy estimate of freedom from rats A very complete Inspection Report was drawn up in which the evidence of rat presence in the ship, hold by hold space by space, was to be stated as—none, old, fresh (slight, 1–5 rats, moderate, 5–10, marked, over 10) The signs of rat infestation depended upon were rat droppings, rat runs gnawed woodwork, damage to cargo, rat nests, and rats, alive or dead After this Report had been filled up for 100 ships in which on subsequent fumigation in New York Harbour the number of rats found dead corresponded very accurately with the forecasts, it was clear that the method had approved itself, and a larger test of 200 vessels was made Of these, 91 (uninfested) were excused fumigation, while in the other 109, it was estimated 1786 rats existed Actually 1813 rats were found dead in them after fumigation, a discrepancy of less than 2 per cent Accordingly ships found free from rats by the New York inspectors are no longer compulsorily fumigated This is a great advance, for it now becomes the shipowner's interest to eliminate rats from his ships whether by trapping, rat-proofing, or whatnot, and the risk of spread of rat-carried plague over the world is diminished

PROTECTIVE COLOURING IN WAR

THE news of the impending change in the standard uniform of the French army from horizon blue to khaki will excite the interest of the soldier, the scientist, and the sentimentalist No nation has emphasised the trappings of war more than the French, they have even coined a special and untranslatable word for it, *panache* And perhaps no nation has suffered more severely from this appeal to military ardour through the eye, at Waterloo, for instance, Napoleon was led into fatal delay while he passed his army in review, and in the early days of the Great War thousands of French soldiers were unnecessarily sacrificed to the German machine guns by their uniforms of scarlet and blue

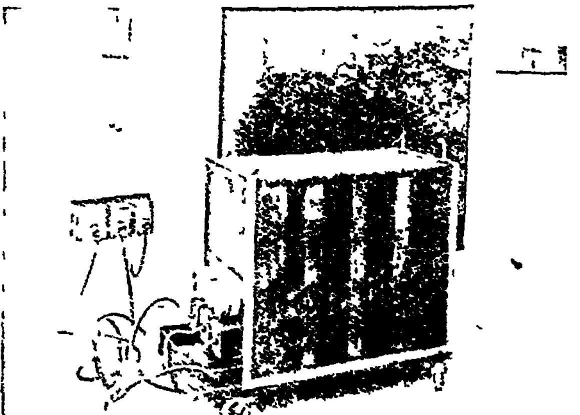
The disadvantage of being conspicuous is sufficiently obvious, but invisibility also has its dangers, and a minor military problem of to-day is to devise new methods of letting the guns know the position of the infantry during an advance, thus preventing occurrences such as the shelling of the crest of Sari Bair after our own men had won it from the Turks

If invisibility is to be the criterion for the colour of a field service uniform, the soldier may well ask what is the scientific evidence which has led to the adoption of khaki by the great majority of the nations Protective mimicry in the animal world merely demonstrates that to be seen with difficulty an object must resemble its background, few natural backgrounds are uniform in colour, so most animals which strive after invisibility are of mixed or variegated shades In this connexion Gérard and Devismes recently tested the visibility of targets of different colours against various backgrounds under various conditions of light [1] The colours chosen were scarlet, green, royal blue white, mouse grey, and dead-leaf brown As might have been expected, mouse grey and dead-leaf brown (defined as the colour of a withered beech leaf) were by far the least conspicuous Between these two there was no practical difference If we grant, however, that grey or brown is less generally visible than blue, the question arises as to which shade of grey or brown is the best and on this point, so far as we know, there is no scientific evidence

The original khaki was introduced for service in India by the Guides about 1848, and was a light dust colour with a hint of orange (Urdu *khak*, dust) With its adoption as a field service dress for the whole army a shade of green crept in, and during the late war almost every variation could be seen The United States and Irish Free State armies emphasise the greenish tint, while the French Colonial army has introduced a rather dark brown element What is required is some research into the production of a tint which will have the greatest possible invisibility under the greatest number of conditions Perhaps the uniform of the future will resemble the young plover in colour, having a pepper-and-salt ground with dark blotches Meanwhile, anyone who has seen a Franco-British attack and remembers, as he must, the long dim khaki lines change suddenly to the challenging horizon blue, will congratulate the French Army on a very wise change

ELECTRIC HEATING INSTALLATION IN AN OPERATING THEATRE

A SUCCESSFUL method of utilising electricity for special heating purposes in exceptionally difficult circumstances has been applied in respect to the operating theatre of the Harwich and District Cottage Hospital This hospital is equipped with a central heating system, and in order that the operating theatre should be kept at a suitable temperature, it was found necessary to keep the main boiler going practically all the year round and at times when it was not required for the general heating of the hospital The problem which faced the managerial staff was to raise the temperature of the operating theatre during periods when the main system was shut down and extra heat was necessary, the process to occupy about 30 minutes The problem was accentuated by the fact that whatever system was employed, owing to the lack of space, the apparatus after performing its duties would have to be of a type easily and quickly removable The solution was the adoption of the portable electric radiator shown in the illustration, which has been a success The apparatus is of the "Magnet" type manufactured by the General Electric Co, Ltd, is loaded to 12 k w, and the desired temperature is raised well within the time required A tray is provided for the flexible tubing so that it may be quickly disposed of when the radiator is wheeled out of the theatre



PRINCESS MARY AT HOSPITALS—Last week Princess Mary had two hospital engagements On Tuesday she opened, at the Kent County Medical Hospital at Barming, near Maidstone, a new nurses' home, which has cost £50,000, and has accommodation for 110 nurses, and on Wednesday she opened the Queen Alexandra wing of the King-Edward Memorial Hospital at Ealing

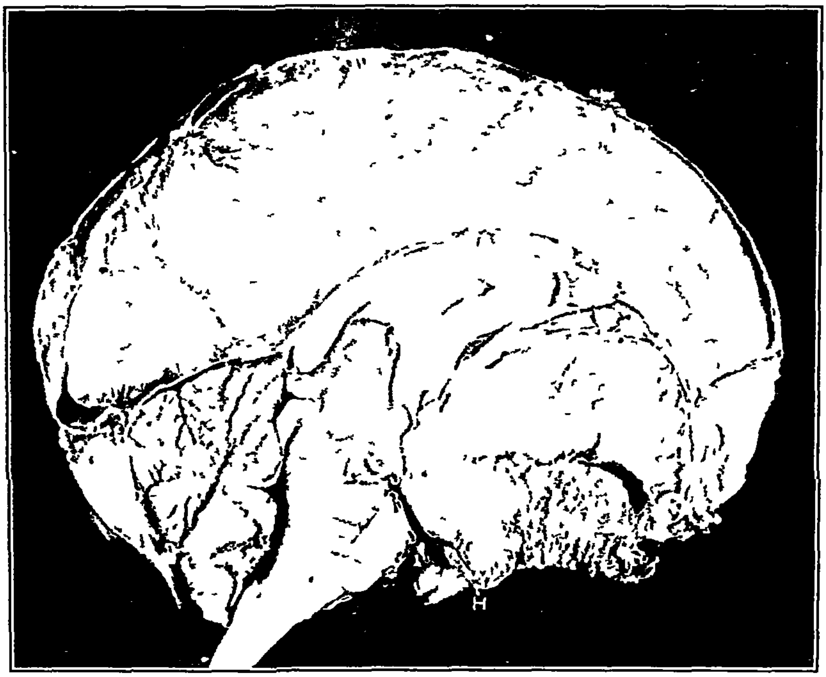
FIG 4



Photograph of the tumour in the author's first case (1911) of olfactory groove meningioma (undiagnosed) Note the backward prolongation of the tumour projecting into the pituitary fossa and flattening the hypophysis (H)

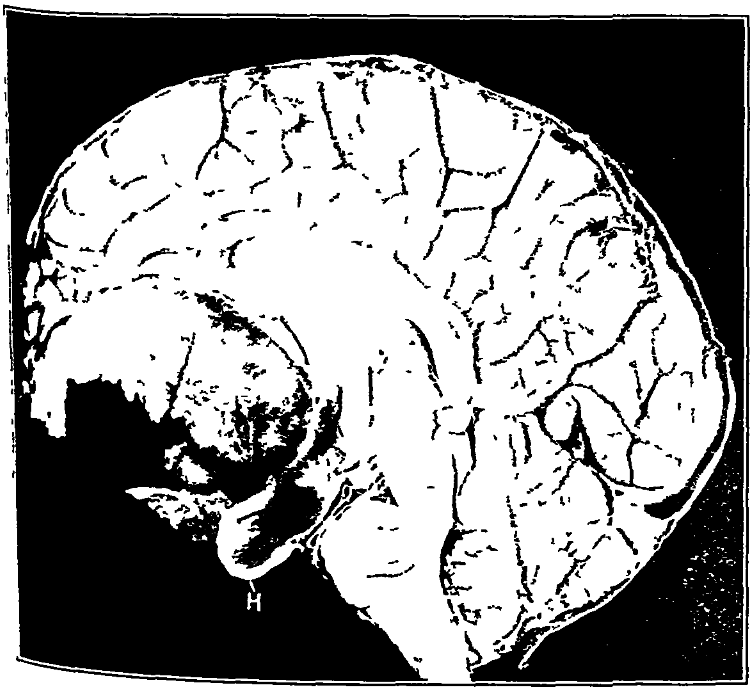
Surg No 15922 *Olfactory-groove meningioma with the syndrome of homolateral optic atrophy, contralateral papillœdema, anosmia, and mental deterioration Partial first-stage excavation and complete second stage removal of growth Sacrifice of bone-flap Recovery* —On Jan. 13th, 1922, Mrs S M, aged 62, was referred to the Brigham Hospital on the advice of Dr Charles H May, of New York, with the complaint of failing mentality and loss of vision

Anamnesia —She had enjoyed excellent health until the midsummer of 1920 when a reduction in vision was first observed By January, 1921, this had progressed to practical blindness in the left eye At this time the fundus in the affected eye showed little change, whereas in the other eye a low grade of papillœdema was present A diagnosis of retrobulbar neuritis had originally been made, but as the papillœdema in the right eye progressed and the nerve-head in the left began to show evident pallor, doubts were felt She was seen in consultation by many persons who made various suggestions, such as aneurysm of the internal carotid, ethmoidal disease, frontal tumour, pituitary tumour An extensive intranasal operation was finally performed without disclosing a trace of infection. This was followed by a prolonged series of X ray exposures of the pituitary region Meanwhile evidences of mental deterioration began to appear, shown by untidiness, loss of memory, euphoria, and other dispositional changes

Examination on Admission —This was quite negative apart from the neurological findings She was a well-nourished and vigorous-appearing woman who admitted no discomforts To be brief, she was found to have (1) *complete anosmia* (which so far as could be told had been lost before the intranasal operation), (2) *a primary atrophy of the left optic nerve* with total blindness, (3) *an atrophic pallor of the left optic nerve, apparently secondary,* vision being reduced to 2/200 and visual fields impossible to take, (4) *mental symptoms* shown in slow cerebration euphoria with incoöperation, loss of memory for recent events, occasional disorientation, and impairment of concentration, (5) *exceedingly inactive deep reflexes*, (6) slight *erosion of the wing of the left sphenoidal ridge* and *pressure enlargement of the sella* shown by the X ray

The presumptive diagnosis of an endothelioma arising from the left olfactory groove was made, and on Jan 20th, under ether-anæsthesia, a low left frontal osteoplastic flap was reflected, the extracerebral tissues being highly vascular An extremely tense dura was disclosed and an immediate subtemporal decompression was made The exploratory brain-needle detected a large firm tumour occupying a large portion of the frontal lobe The bone-flap was replaced for a second session.

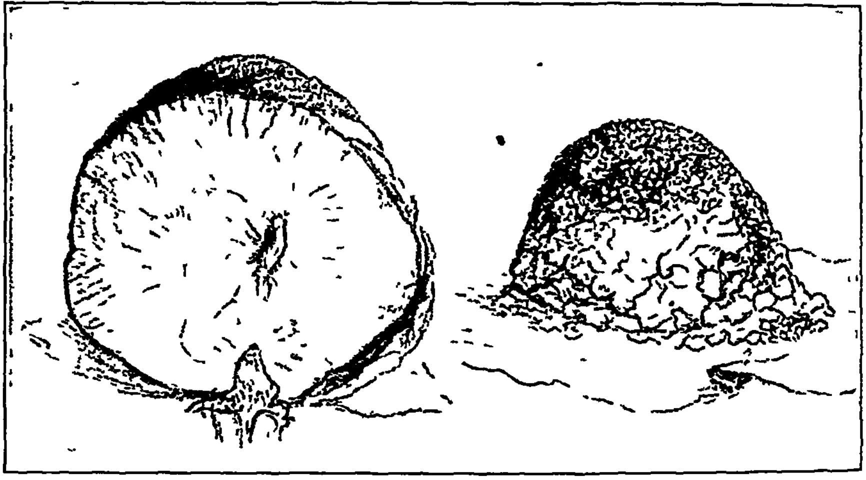
FIG 5



(Cf Fig 4) To show the "nest" in the right frontal lobe after removal of the right half of the symmetrical lesion (cf Fig 6) Note (1) the flattened cup shaped hypophysis (H) (2) the elongated and compressed infundibulum and distorted third ventricle, (3) the ridge made by the elongated anterior communicating artery passing up from the internal carotid.

On the 28th the flap was again reflected and the dura opened along the margin of the sagittal sinus At the lower part of the field the anterior pole of the tumour was disclosed The growth was so nodular and irregular in shape that the brain could not be brushed away from it easily What is more, it proved to be of such an unexpectedly large size that to remove it intact would have caused, through dislocation and contusion, irreparable damage to the enveloping nervous tissue Consequently, the intracapsular method of enucleation, long put in use in the surgical treatment of acoustic tumours, was called upon to get us out of our difficulties Accordingly, with a sharp spoon, However, the lesions prove by no means to be rare Another case of precisely the same kind came to autopsy on March 15th, 1921, after an ineffectual decompression at my hands for an unlocalised (and at the time unlocalisable) tumour The accompanying photographs (Figs 7 and 8) will show how closely the growth resembles the preceding one, its point of origin from the olfactory groove being more apparent as the lesion was not broken in removal (cf Figs 8 and 4), and the photograph of its under surface shows the prolongation of the lesion into the pituitary fossa with backward displacement of the chiasm

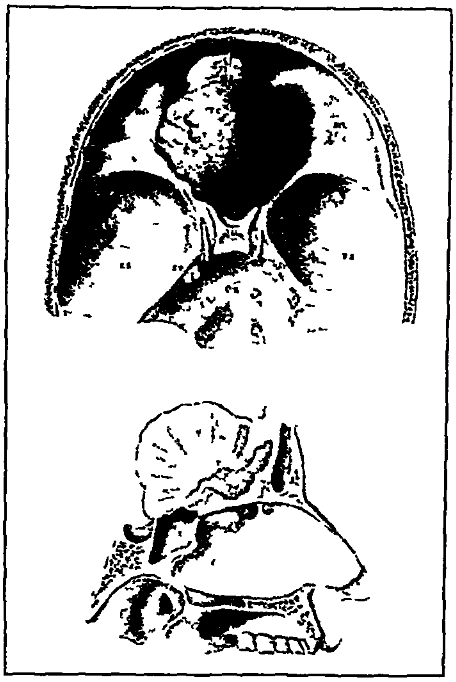
FIG 1



Cleland's sketch showing (1) the tumour on coronal section with the position of the crista galli and the small central area of calcification, (2) the characteristic, finely granular external surface of the lesion

My curiosity naturally enough was aroused by the similarity of these two lesions, and during the intervening years I have gathered, from one source or another, photographic records of other cases, some of which may be here reproduced in order to emphasise how closely in their situation and gross appearance these tumours resemble one another (Figs 9-14) The specimens for the most part represent post-mortem disclosures on patients who, because of mental symptoms, had come to be confined in asylums for the insane and in whom the presence of tumour was unsuspected

FIG 2

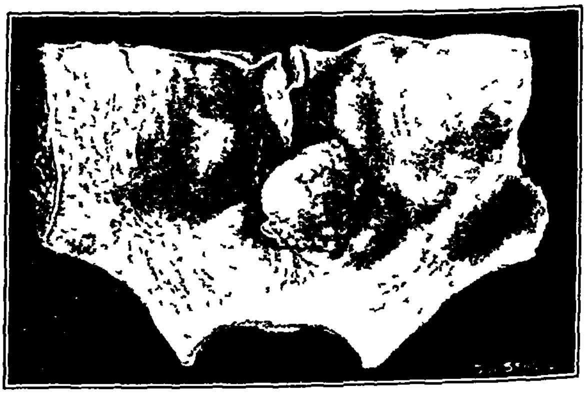


Cruveilhier's illustration (1835) of an olfactory groove meningioma called a ' tumeur cancéreuse des meninges "

Meanwhile our knowledge of these meningiomas of the anterior fossa was increasing year by year so that they could be diagnosed correctly, and now and again one of them was exposed at operation, but at best only partially removed Under ordinary circumstances every effort is made to enucleate a meningeal tumour intact even at the risk of causing greater damage to the brain than would a piecemeal removal But in dealing with one of these large subfrontal tumours the likelihood of further damage to the already impaired mental functions through contusions of the frontal lobe makes such a procedure one of questionable propriety

These meningiomas of the frontal base, as I have said, are apt to be firm and psammomatous in character, and finally in a desperate attack on one of them which happened to be largely unilateral I had been forced into what for me at least, was a new manœuvre, whereby the firm and comparatively non-vascular lesion was gutted or cored, leaving its partly collapsed rind to be removed at a second session Since it was this manœuvre that suggested the adoption of electro-surgical methods for accomplishing the same end with less risk, I shall report the case in full The history, which among other things shows the importance for diagnosis of a chronologically exact sequence of symptoms, will serve as a contrast to the case-history to follow

FIG. 3

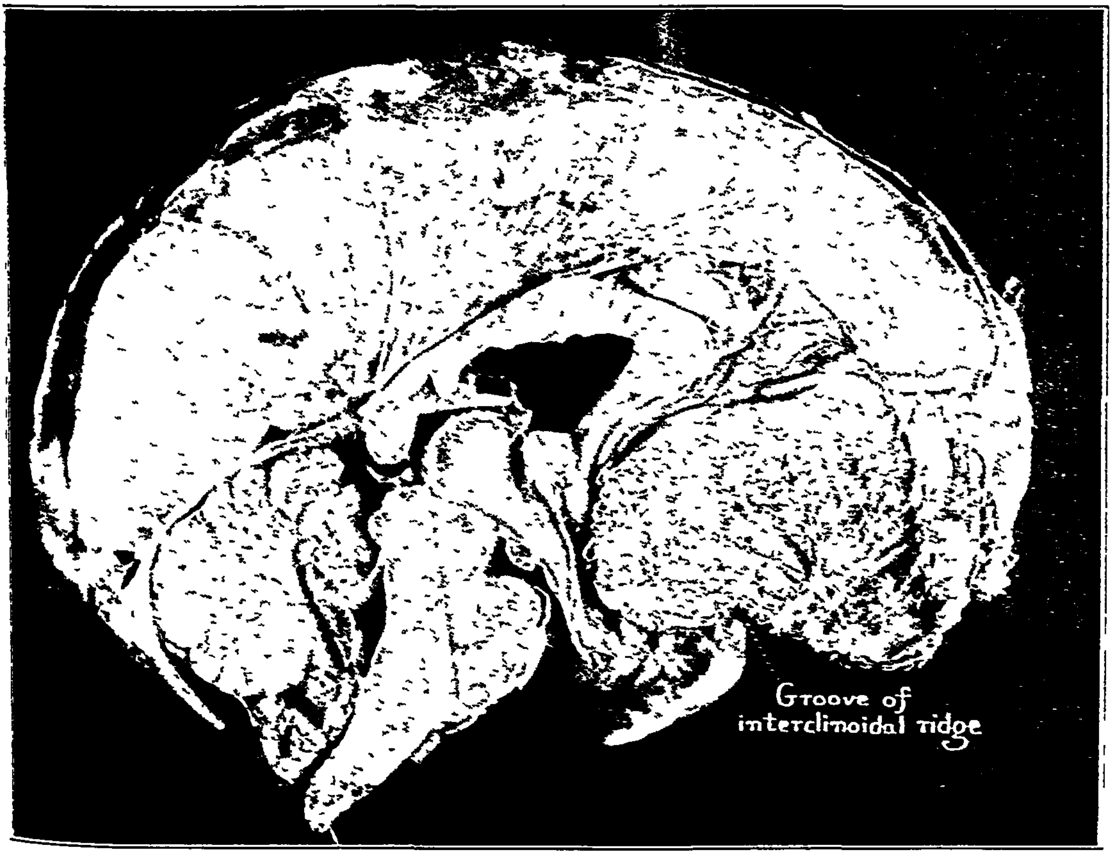


Small olfactory groove meningioma (natural size) from the Museum of the Royal College of Surgeons (London) Kindness of Prof Shattock and (5) also from the same cause, mental symptoms due to compression and deformation of the left frontal lobe

To this particular syndrome attention was first called by Foster Kennedy in 1911 in an article with a somewhat misleading title[7] in which a variety of lesions such as subfrontal abscesses and tumours of various kinds had caused unilateral loss of the sense of smell with an ipsolateral optic atrophy due to direct pressure, and contralateral choked disc due to intracranial tension. In the first of his cases, which had been observed on the service of Sir William Gowers at the National Hospital, Queen-square, there was found at autopsy, after a fatal operation, a subfrontal endothelioma which was said to have originated from the dura over the crista galli.[8]

The tumour in Dr. Kennedy's case, of which he has kindly given me a photograph (Fig. 11), proves to be a bilaterally symmetrical, or fairly symmetrical, meningioma, whereas in the case I have just described in such detail the lesion was largely unilateral. The bilaterally disposed lesions are apparently more common and I know of only one good example in the literature of a large unilateral meningioma of the olfactory groove accompanied by satisfactory illustrations. This case was reported by Blackburn and Hough some years ago[9] The patient was a coloured woman, 36 years of age, who died in the Government Hospital for the Insane. The brief clinical history states that she had been blind for some time, that she had been having epileptiform convulsions, and that there was marked mental impairment which reached an extreme degree of dementia before the end. Tumour was unsuspected. The illustrations show (Figs. 20 and 21) that the growth chiefly involved the right frontal lobe, though the left was markedly indented by it. The tumour, so far as I can judge, occupied precisely the same situation as that removed in the patient under discussion.

FIG. 8



Median section of tumour in author's second case for comparison with Fig. 4. Note the overhang of the tumour posterior to groove of inter-clinoidal ridge; also the cross-section of the anterior communicating artery at the posterior border of the lesion.

Since the weight of this tumour figured by Blackburn and Hough was only 140 g., whereas the total weight of Mrs. M.'s tumour was 204 g. (cf. Figs. 20 and 19), some idea is thereby given of the magnitude of the undertaking. For the removal of this tumour three hazardous major operations were necessitated, with ultimate sacrifice of the bone-flap, leaving an ugly scar. Seven hours, all told, were expended at the operating table, and untold hours at the complicated daily dressings during the tedious postoperative period of cerebro-spinal drainage, all of this necessitated an unduly prolonged hospital sojourn.

My reason for dwelling in such detail upon the operation in this case is for the purpose of contrasting it with a present-day operation upon one of the still more inaccessible bilaterally-placed olfactory-groove meningiomas. As will be seen, the operation can be

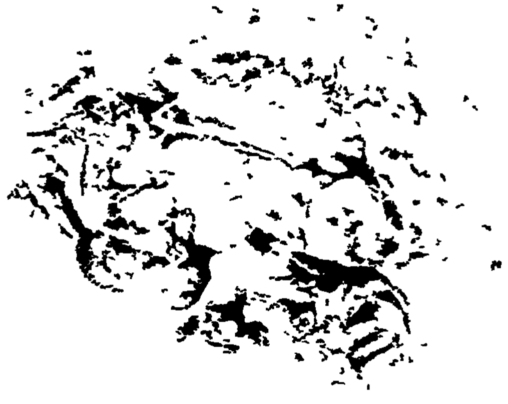
FIG 6.



The right half of the tumour (natural size) removed from its in the right frontal lobe Note (1) the finely nodular face, (2) the rounded prominence in the lower left field, th mould of the hypophysial cup (Cf Fig 5)

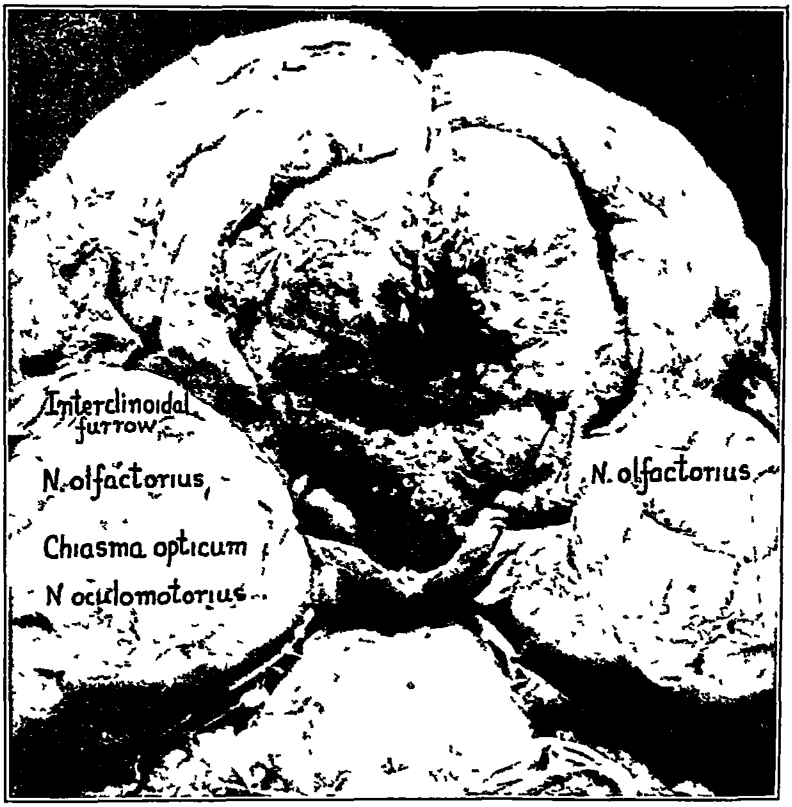
cup-shaped fragments were scooped out of the anterior pole of the tumour until a large cavity was produced This was a tedious procedure, since it was necessary, after the removal of each fragment, to delay until bleeding from the raw surface could be checked All told, an amount of tissue (Fig 15) weighing 78 g was thus removed The patient's blood pressure by this time had begun to fall off and it was deemed wise to postpone the attempt to dislodge the remaining mass of the growth for a third session

A sufficiently generous excavation of the tumour had been made to permit the firm encircling edges of the cavity to be collapsed and sewed together The sutures were left long so that they could be tugged upon in the hope thereby of drawing the growth forward at the subsequent operation should she survive to have one In withdrawing from the incompleted enucleation not only was it impossible because of the contusion and œdema of the frontal lobe to resuture the dura, but it was found that it would even be dangerous to replace the osteoplastic flap without risk of compression. Consequently the cranial portion of the flap had to be sacrificed and the scalp alone was closed over the raw surface protected merely by an intervening layer of gutta-percha tissue At the conclusion of the operation, owing to loss of blood, transfusion was necessary, and it was some hours before she was regarded as out of danger

The convalescence was stormy Owing to tension the wound barely held, and fearing that it might part and a fungus cerebri develop unless the remaining portion of the tumour was soon removed, we were forced into a final-stage operation on the ninth day

Accordingly, on Feb 6th, the flap was again reflected and the tumour exposed By drawing upon the previously-placed sutures the remaining portion of the growth could be held while the nervous tissues were being brushed from its smooth surface, it was finally drawn forward and tilted out of the wound (Fig 16) Some bleeding occurred from the primary point of attachment in the right olfactory groove, but this was promptly checked by the placement of raw muscle obtained from an operation on another patient There was a considerable fall in blood pressure, but on the whole this final stage was better borne than either of the preceding ones After as complete hæmostasis and as careful toilette of the wound as possible, the scalp was replaced and the wound resutured as accurately as the unfavourable circumstances permitted

FIG 7.



The author's second clinically unrecognised case, showing the under surface of the lesion Note the median position of the tumour, cleft anteriorly by the falx, the median dark area corresponding to the olfactory-groove attachment of the growth the transverse groove in the tumour between the ends of the widely separated olfactory nerves made by the inter clinoidal ridge, the overhang of the growth filling the pituitary fossa and crowding the chiasm backward Weight of tumour 82 g

The convalescence was again stormy Where the edges of the flap had become thinned by tension a cerebro spinal fluid fistula developed, and it was six weeks before this had closed Not until April 2nd, nearly three months after her admission, could the patient be safely discharged It had been a long battle and, though symptomatically she was a transformed individual with normal mentality and a marked and most unexpected improvement in vision, she was left with an ugly frontal cicatrix which was ill-concealed by wearing the hair low on the forehead (Figs 17 and 18)

The end-result has been excellent. Practically normal fields with reading vision have been restored to the right eye and ability to count fingers in the previously blind eye At this present writing, five years later, she remains well and is leading, for her years, an active life

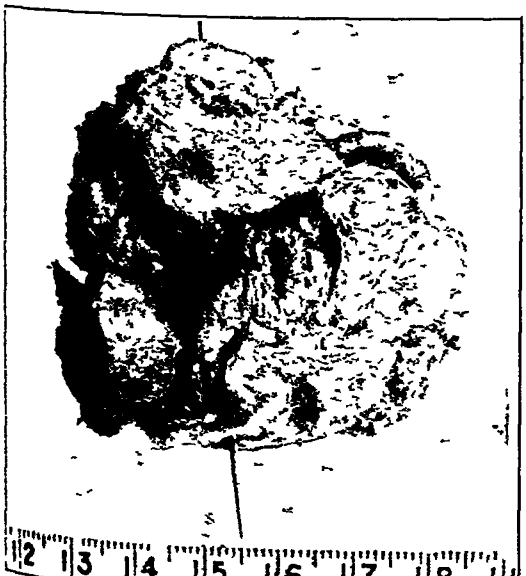
Some idea of the total bulk of the 78 g fragments removed at the first session and of the 126 g portion subsequently removed may be gained from the photograph (Fig 19) of the tissues laid in position on the base of an adult skull

Here, then, was a woman of advancing years with a combination of symptoms which in all probability appeared in the following chronological order (1) a primary left anosmia (unobserved), (2) a homolateral failure of vision due to a primary optic atrophy caused by direct pressure on the left optic nerve, (3) complete anosmia (observed) due to further enlargement of the growth implicating the right olfactory bulb, (4) an increase in intracranial tension from the same cause with consequent papillœdema of the right optic nerve, brain tumours, it being particularly adaptable to the meningiomas

Electrical currents of one form or another under the general term of diathermy have been utilised for therapeutic purposes in both medicine and surgery for nearly 20 years The underlying principle concerns the generation of heat in the tissues when a current is passed through them because of the electrical resistance which they offer I need not go into the history of the subject other than to recall the announcement in 1907 by Prof. Pozzi, of Paris, that certain superficial and even some deep-seated malignant growths might be effectively destroyed by the action of sparks of high frequency and high tension given off from the terminal of Oudin's resonator This original procedure, called fulguration, in which the tissues to be attacked were "sparked" from a distance, has in later years become so far developed and improved upon that local dehydration and coagulation of the living tissues can now be produced by currents brought into direct contact with them.

For these purposes alternating currents of exceedingly high frequency are employed Whereas, the ordinary alternating current supplied by the usual city power plant changes its direction of flow 120 times a second, in the usual electro-surgical apparatus the current oscillates several hundred-thousand times a second Such a rapidly oscillating current has been shown to have no effect on the tissues other than of heating and cutting, the familiar physiological reactions produced by low-frequency alternating currents being absent Since, by the employment of a small ("active") electrode and a large ("indifferent") electrode, all the cutting effects can be confined to the tissues in the immediate vicinity of the active electrode, it constitutes a surgical tool which bids fair to replace the scalpel in certain fields of work.

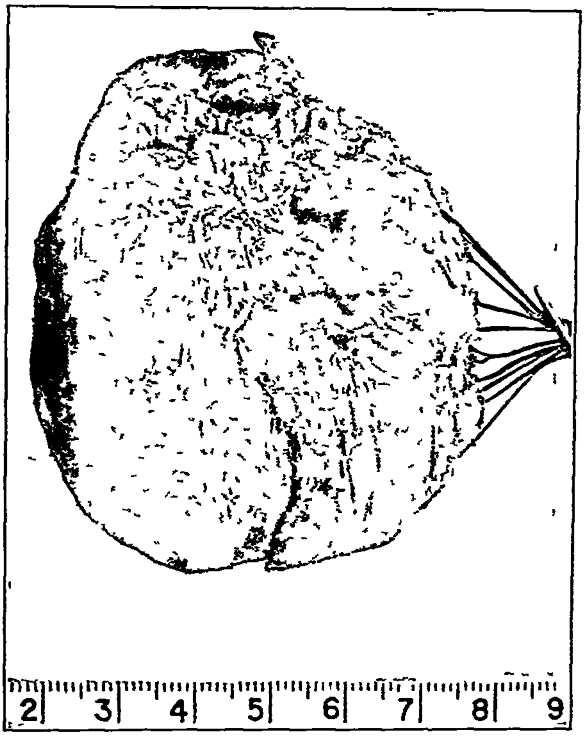
FIG 15



Case 1 Fragments (natural size), weighing 78 g, pieced together after being excavated from the anterior pole of a large unilateral olfactory-groove meningioma

Naturally enough, following Pozzi's lead, this new adjunct to surgery has for obvious reasons been chiefly restricted to the removal of malignant growths and has, therefore, remained largely in the hands of specialists who are called upon to treat malignant disease in inaccessible places Those who have previously employed these methods in the extirpation of carcinoma about the mouth and other body orifices have written enthusiastically on the subject But meanwhile, owing to the variety of trade names which have been introduced, no little confusion has arisen as to the meaning of fulguration, diathermy, endothermy, and so on No less has there been confusion in regard to the various forms of current that are employed, whether unipolar or bipolar, whether for cutting, dehydration, or coagulation For purposes of simplification, therefore, it would seem better for the time being to utilise the single term of electro-surgery for all these varied performances

FIG 16.



Case 1 Lateral view of posterior portion of tumour removed at second stage operation This is a smooth-surfaced meningioma of the more rapidly growing variety without psammomatous changes

The general surgeon, by long tradition wedded to the scalpel, will doubtless be slow in adopting this novel procedure Only a small part of his work has to do with malignant disease, and I confess to have been somewhat sceptical about the adaptability of this new procedure to my own purposes after having made a few trials with the form of apparatus on the market in which the single tool was a needle to be used either to part the tissues by dehydration, or to char and coagulate them

To my colleague, Prof W T Bovie, Director of the Biophysical Laboratories of the Cancer Commission of Harvard University, I am wholly indebted for my renewed interest in the subject, and for what little I know of the physical principles involved Dr Bovie has interested himself in perfecting, for use in the Collis P Huntington Memorial Hospital, an electro-surgical apparatus in which both the coagulating and cutting currents are combined in one machine, and, through the agency of a pistol grip which he has devised, the current can be conveniently let on or off by the operator's finger pressing a trigger In this machine the high frequency of oscillation has been increased from the usual five- or seven-hundred thousand cycles a second used in diathermy, to a million and a half cycles so that the current is not only far more powerful than any which has been so simplified by the technical device to be described, that it can be carried through at one session with preservation of the bone-flap and an invisible scar But the underlying principle remains the same—namely, the partial intracapsular excavation of the tumour in order that its walls may be collapsed and the large growth be brushed away from the brain and removed with minimal contusion of the nervous tissues The removal of the meningioma intact has ordinarily in the past, as already told, been the desired goal of operation To accomplish this, even when the growth is in a situation easily approached, may be a formidable undertaking because of the great vascularity of the adjacent tissues It consequently is loss of blood that makes successive-stage operations more often necessary in the case of the meningiomas than of any other variety of brain tumours

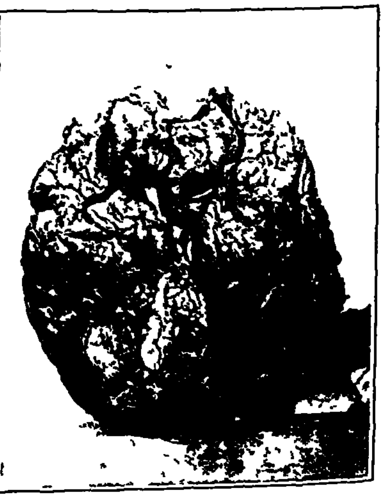
FIG 14



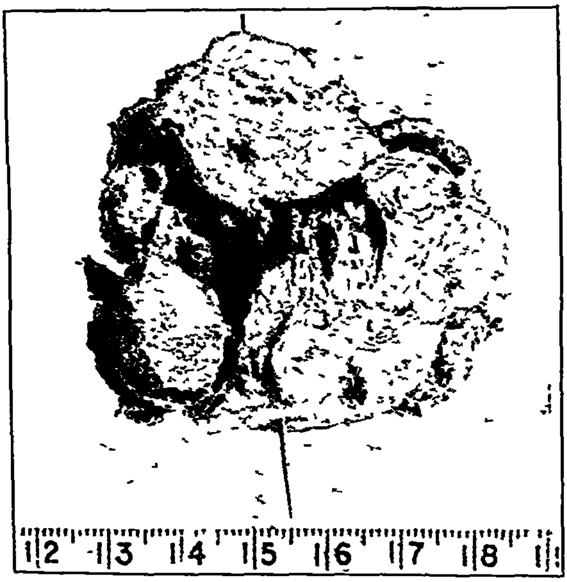
Case reported by C E Royce as sarcoma of the base of the skull, Jour Amer Med Assoc, 1916, lxvi, 1288

The great problem, then, is to control and to diminish the effects of bleeding so far as possible Among the devices towards these ends may be mentioned the use of silver clips, of muscle implantation, of tissue-fixation in situ, and, if necessary, the *coincidental or subsequent employment* either of blood transfusion or of refusion with the patient's own blood which has been collected from the wound by a suction apparatus Latterly, still another principle, that of electrical surgery, has come to be employed not only as a means of perfecting hæmostasis in intracranial operations in general but as a direct aid to the successful extirpation of certain brain tumours, it being particularly adaptable to the meningiomas.

Electrical currents of one form or another under the general term of diathermy have been utilised for therapeutic purposes in both medicine and surgery for nearly 20 years. The underlying principle concerns the generation of heat in the tissues when a current is passed through them because of the electrical resistance which they offer. I need not go into the history of the subject other than to recall the announcement in 1907 by Prof. Pozzi, of Paris, that certain superficial and even some deep-seated malignant growths might be effectively destroyed by the action of sparks of high frequency and high tension given off from the terminal of Oudin's resonator. This original procedure, called fulguration in which the tissues to be attacked were "sparked" from a distance, has in later years become so far developed and improved upon that local dehydration and coagulation of the living tissues can now be produced by currents brought into direct contact with them.

For these purposes alternating currents of exceedingly high frequency are employed. Whereas, the ordinary alternating current supplied by the usual city power plant changes its direction of flow 120 times a second, in the usual electro-surgical apparatus the current oscillates several hundred-thousand times a second. Such a rapidly oscillating current has been shown to have no effect on the tissues other than of heating and cutting, the familiar physiological reactions produced by low-frequency alternating currents being absent. Since, by the employment of a small ("active") electrode and a large ("indifferent") electrode, all the cutting effects can be confined to the tissues in the immediate vicinity of the active electrode, it constitutes a surgical tool which bids fair to replace the scalpel in certain fields of work.

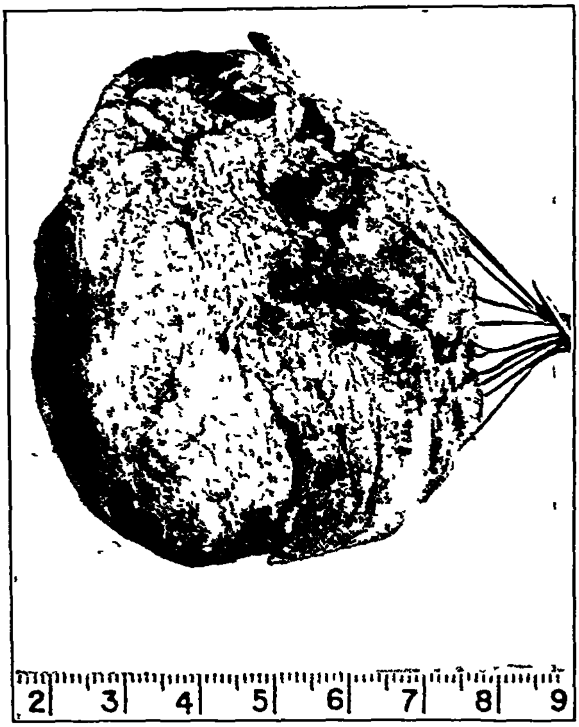
FIG 15.



Case 1 Fragments (natural size), weighing 78 g., pieced together after being excavated from the anterior pole of a large unilateral olfactory-groove meningioma.

Naturally enough, following Pozzi's lead, this new adjunct to surgery has for obvious reasons been chiefly restricted to the removal of malignant growths and has, therefore, remained largely in the hands of specialists who are called upon to treat malignant disease in inaccessible places. Those who have seriously employed these methods in the extirpation of carcinoma about the mouth and other body orifices have written enthusiastically on the subject. But meanwhile, owing to the variety of trade names which have been introduced, no little confusion has arisen as to the meaning of fulguration, diathermy, endothermy, and so on. No less has there been confusion in regard to the various forms of current that are employed, whether unipolar or bipolar, whether for cutting, dehydration, or coagulation. For purposes of simplification, therefore, it would seem better for the time being to utilise the single term of electro-surgery for all these varied performances.

FIG 16



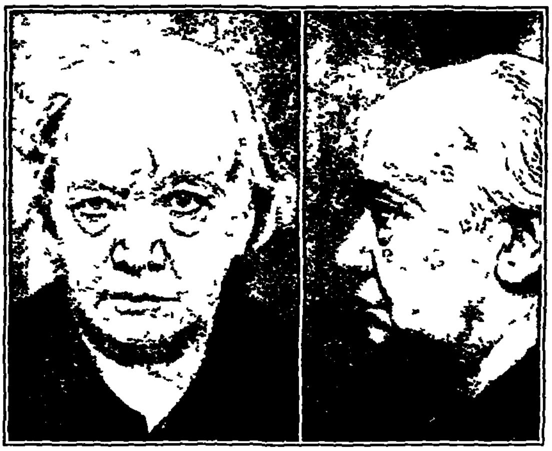
Case 1 Lateral view of posterior portion of tumour removed at second-stage operation. This is a smooth-surfaced meningioma of the more rapidly growing variety without psammomatous changes.

The general surgeon by long tradition wedded to the scalpel, will doubtless be slow in adopting this novel procedure. Only a small part of his work has to do with malignant disease, and I confess to have been somewhat sceptical about the adaptability of this new procedure to my own purposes after having made a few trials with the form of apparatus on the market in which the single tool was a needle to be used either to part the tissues by dehydration, or to char and coagulate them.

To my colleague, Prof W. T Bovie, Director of the Biophysical Laboratories of the Cancer Commission of Harvard University, I am wholly indebted for my renewed interest in the subject, and for what little I know of the physical principles involved. Dr Bovie has interested himself in perfecting, for use in the Collis P Huntington Memorial Hospital, an electro-surgical apparatus in which both the coagulating and cutting currents are combined in one machine, and, through the agency of a pistol grip which he has devised, the current can be conveniently let on or off by the operator's finger pressing a trigger. In this machine the high frequency of oscillation has been increased from the usual five- or seven-hundred thousand cycles a second used in diathermy, to a million and a half cycles so that the current is not only far more powerful than any which has been heretofore used, but by a modification of its character the degree to which the incised tissues are coagulated (dehydrated) may be controlled. The current, moreover, is so powerful that, for purposes of cutting and coagulating, a loop may be employed rather than, or at times in place of, the straight needle in common use

When I first had the good fortune to see this loop being used bloodlessly to scoop out bits of tissue from a malignant tumour for purposes of biopsy, I foresaw that a new tool had been put into our hands to facilitate the piecemeal removal of at least some of the heretofore inaccessible intracranial tumours With Dr. Bovie's cooperation, during the past few months I have gained sufficient familiarity with the instrument to realise that it holds out untold possibilities for the future of neuro-surgery For the purposes of this address it will suffice to report a single experience with one of the hitherto inoperable, bilaterally-placed olfactory-groove meningiomas such as occur in the preceding photographs (cf Figs 9–14) When compared with the account just given of an operation for a far more accessible tumour of like kind which was removed without the aid of electro-surgery, the contrast between the old and new methods will be the more conspicuous

FIGS 17 AND 18.



Case 1 Patient after a third-stage operation showing unsightly scar due to necessary sacrifice of bone flap and prolonged cerebro spinal leakage

Surg No 28023 *A patient with the syndrome of bilateral anosmia, optic atrophy, and altered personality A small area of calcification near the olfactory groove disclosed by stereoscopic roentgenograms*—On Jan 18th, 1927, J T, a man 45 years of age, a printer's assistant, was referred to the Peter Bent Brigham Hospital by Dr William C Muncy, of Providence, R I, with the complaint of loss of vision

Antecedent history—Previously a man of good health, the father of a family of healthy children, the patient had first consulted Dr Muncy on March 23rd, 1926, owing to recent obscuration of vision in his right eye A primary optic atrophy was disclosed with symmetrically contracted field, the left eye being quite normal in all respects Nothing was found to account for the condition The Wassermann reaction was negative, the paranasal sinuses were investigated and showed no signs of disease

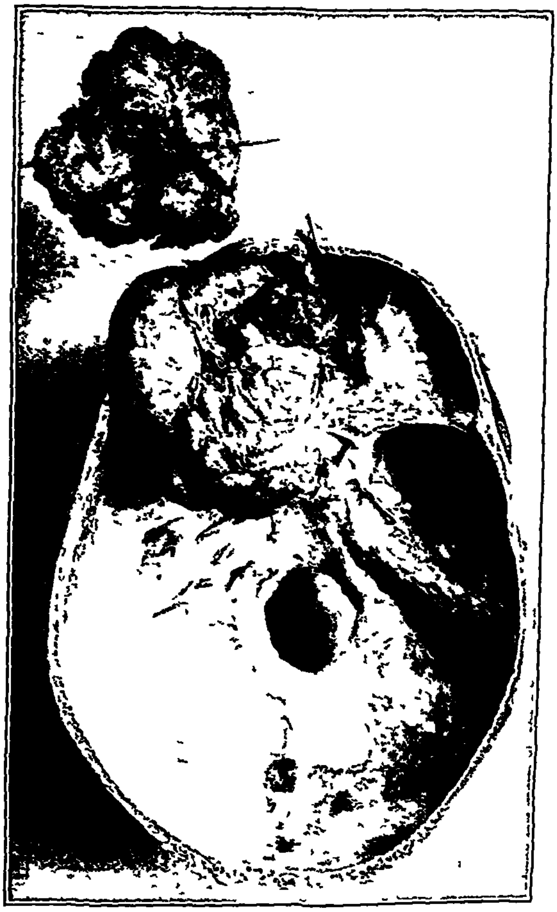
Dr Muncy did not see him again till nine months later, when on Dec 20th, 1926, he reported to say that when leaning over at his work the sight in the left eye had suddenly in like fashion become greatly blurred Owing to poor coöperation and seriously impaired vision a dependable perimetric observation could not be made Sphenoidal trouble was suspected and he was given some intranasal treatments consisting of tamponing with argyrol, &c Since this treatment was ineffective and some absorption of the sella was disclosed by the X ray, a suspicion of pituitary disease was aroused and he was referred, as stated, to the Brigham Hospital

Physical examination on admission—This showed a well-nourished, middle-aged man, whose statements regarding the course of his malady were most unreliable He had an impaired memory for dates and incidents, coupled with a distinct euphoria and indifference to the seriousness of his plight. He was somewhat garrulous and grandiloquent, his manner suggesting an early stage of dementia paralytica. Except for an occasional slight morning headache he disclaimed any physical discomforts whatsoever

Aside from these mental peculiarities the only positive clinical findings were (1) *a complete loss of the sense of smell*, which the patient ascribed to the nasal treatments he had recently received; (2) a *bilateral optic atrophy* with blindness on the right, and vision on the left estimated at 20/200, dependable perimetry being impossible, (3) a possible *right abducens paresis* causing a slight internal squint, (4) the presence of a *minute area of calcification* shown, on stereoscopic roentgenograms, to lie slightly to the left of the midline and about a centimetre above the level of the roof of the orbit. The sella turcica itself was of normal configuration though somewhat atrophic from pressure

Comment—Here, then, was a healthy-appearing individual with obvious mental peculiarities, a complete loss of the sense of smell, an optic atrophy with practical blindness, and a minute patch of calcification just above the left olfactory groove, whereas his primary complaint had been loss of vision on the right. The importance in a case of this kind, of a precise clinical history with the symptoms in their exact chronological order cannot be over-emphasised If we may presume to reconstruct the history in the light of the operative findings, he had had for months or years, unobserved, a relative anosmia primarily affecting the right side This had been followed in course of time by a right-sided primary optic atrophy due to direct pressure on the optic nerve near the

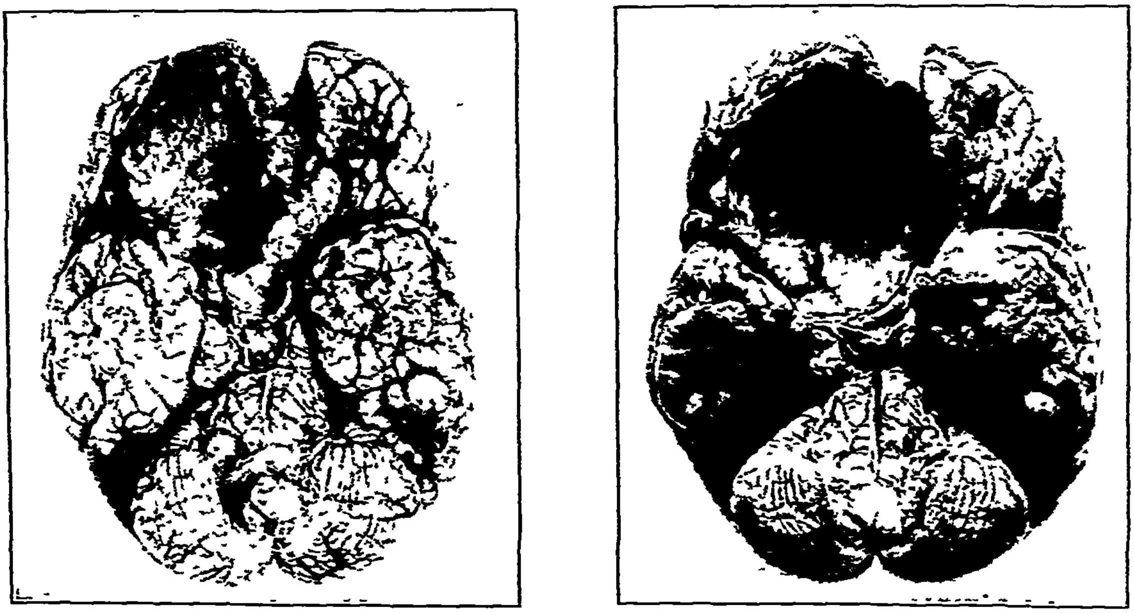
FIG 19



Case 1 The two portions of the tumour removed in successive stages placed upon an adult skull to give some idea of the size and position occupied by the 204 g lesion

foramen. The lesion had finally enlarged sufficiently to produce complete bilateral anosmia to affect the other optic nerve by an increase of intracranial pressure, and to cause indefinite frontal lobe symptoms.

Figs. 20 and 21



Case reported by Blackburn and Hough as an "endothelial spindle-celled sarcoma of dura mater" Tumour was not suspected New York Med. Jour, April 7th, 1906 lxxxiii 692 It is a largely unilateral lesion of the type of Case 1 Fig 20 shows the base of the brain before, and Fig 21 after, removal of the tumour from its bed.

In retrospect the diagnosis is easy enough In reality it was far from being so. It was extremely difficult in the first place to tell whether the optic atrophy was actually primary or, in view of the haziness of the disc outlines, whether it represented a slowly advancing atrophy due to a low grade of papillœdema. What is more, the symptoms had originally appeared on the right side and yet the small shadow detected by the X ray, suggesting calcification in a tumour and presumably, therefore, in its oldest portion or stalk, lay to the left of the median line.

Curiously enough, in accordance with the surgical tradition that unusual cases appear in pairs, there entered the hospital two days after J. T.'s admission another patient, a woman, who ultimately proved to have an exactly similar and symmetrically placed olfactory-groove meningioma. In her case the condition was less advanced and yet it was known that she had unaccountably lost her sense of smell for a period of at least five years. She, too, was found to have a minute patch of calcification which lay just above the olfactory groove on one side of the midline. but in her case there was unmistakably a low grade of papillœdema which had not advanced to atrophy and had not as yet affected vision

The fact that surgical intervention in these two patients was postponed for nearly three weeks after their hospital admission shows how uncertain we were as to the propriety of undertaking a procedure desperate at best, and which if unsuccessful would certainly have made their status much worse than before. It was even difficult to tell from which side the lesion should be approached, for though in the case of J. T the symptoms suggested that the growth was primarily right-sided, yet the patch of calcification lay to the left of the midline.

A tumour of the sort which was visualised in these two patients, however it might be approached, offered by ordinary methods of procedure a surgically hopeless problem. However, on the bare possibility that the anterior pole of the lesion could be brought into view sufficiently well to be attacked with the electric loop, and in the hope that it would prove to be not only a meningioma but one of sufficiently firm consistency for its shell to be finally withdrawn after excavating its central portion, I screwed up my courage to operate upon the first of these patients

Feb 10th, 1927: *Operation Piecemeal total removal, aided by electro-surgical methods, of 60± g more or less symmetrically placed meningioma, though evidently arising from the right olfactory groove. Seven-hour operation. Transfusion. Recovery.*—Under novocaine-anæsthesia the usual low frontal osteoplastic flap was reflected without incident, disclosing a tense dura. On elevating this from the roof of the orbit and carrying the separation down part way to the sphenoidal ridge, the lower anterior margin of a dense tumour could be palpated. What is more, the posterior *part of the orbital roof and the adjacent sphenoidal ridge* were found to be defective owing to the pressure absorption. Because of the discomforts occasioned by elevation of the tense frontal dura to this depth it was necessary to administer ether-anæsthesia.

An incision was finally made through the tense dura, well down under the frontal lobe, and the margin of a meningioma was disclosed. I had but a faint conception at this stage of the procedure of what a task we had before us, but with a dehydrating current I first made a cross-cut in the exposed margin of the tumour and then began to scoop out loopfuls of tissue from the body of the growth.

To make a long story short, it was finally possible to so far excavate the chief mass of the tumour lying to the left of the falx that the outer shell of the growth could be drawn forward and freed from its dense zone of attachment along the deepened and widened olfactory groove of the ethmoidal plate. Only in this area was any troublesome bleeding encountered, and it was easily controlled by using a desiccating current which charred the dura and, at the same time, it is to be hoped, destroyed any remaining nests of tumour cells which remained adherent to it.

On drawing forward the large posterior portion of the growth it peeled away from the cerebral tissues, leaving clearly exposed the elongated and flattened right optic nerve and the adjacent portion of the chiasm as well as the cup-shaped depression in the dura overlying the sella, showing that there were no attachments of the lesion in this situation. The left optic nerve was not seen.

By the removal of this chief mass of the growth from the right side, fortunately with but a minimum of contusion to the frontal lobe, a large cavity was left, which made comparatively easy the subsequent manipulations necessary for the removal of that portion of the tumour lying to the left of the midline This completely blocked the crescentic opening under the falx and hid from view the mesial surface of the left frontal lobe In order to dislodge this remaining portion it was necessary transversely to incise the falx at the upper part of the field and also to detach it from the crista galli which was removed It was then possible to tilt out this last portion of the tumour intact (cf Fig 24), leaving a concave pocket in the hemisphere

After painstaking hæmostasis by the aid of the coagulating current and by the placement of silver clips on a few points which tended to bleed, the huge cavity was filled with Ringer's solution, the bone-flap was replaced, and the scalp was closed in the usual layers without drainage

Second comment —As can be appreciated, this was not a procedure to be done hurriedly, nor could it possibly have been carried through in a single session by any other method I can conceive of Indeed, it could not have been done in multiple sessions as in the case previously described As matters stood, from the time when the scalp was novocainised to the final closure and dressing, seven hours were consumed The patient's condition had remained excellent in spite of the extensive manipulations and some loss of blood, till after the removal of the anæsthetic during the last hour, when the pressures began to fall and the pulse to rise Consequently, while the wound was being closed he was given a transfusion of 500 c cm of blood from a donor, with immediate improvement in his condition

Postoperative notes —The convalescence was without incident He was sitting up on the fourth day The wound healed with a nigh invisible scar (Figs 22 and 23) Almost immediately after the operation he was conscious of better vision in the left eye, and this improved sufficiently so that by the time of his discharge a fairly dependable field could be plotted In spite of a persisting central scotoma he regained sufficient sight to permit him to recognise people and easily to get about alone There also was an almost immediate postoperative improvement in his somewhat obscure mental symptoms

Pathological note —The tumour fragments which were removed weighed, all told, 60 5 g, and taking into account the desiccation produced by the coagulating and dehydrating currents, we may estimate that the growth may have been about an 80-gm meningioma In the accompanying photograph (Fig 24) the chief mass to the left represents the final fragment removed from under the falx out of its cup in the left hemisphere Its surface shows the finely nodular, often mulberry-like character of most of these basilar meningiomas The assembled bits of tissue to the right represent the more or less charred fragments scooped out by the electric loop, some of which are characteristically coiled and worm-like

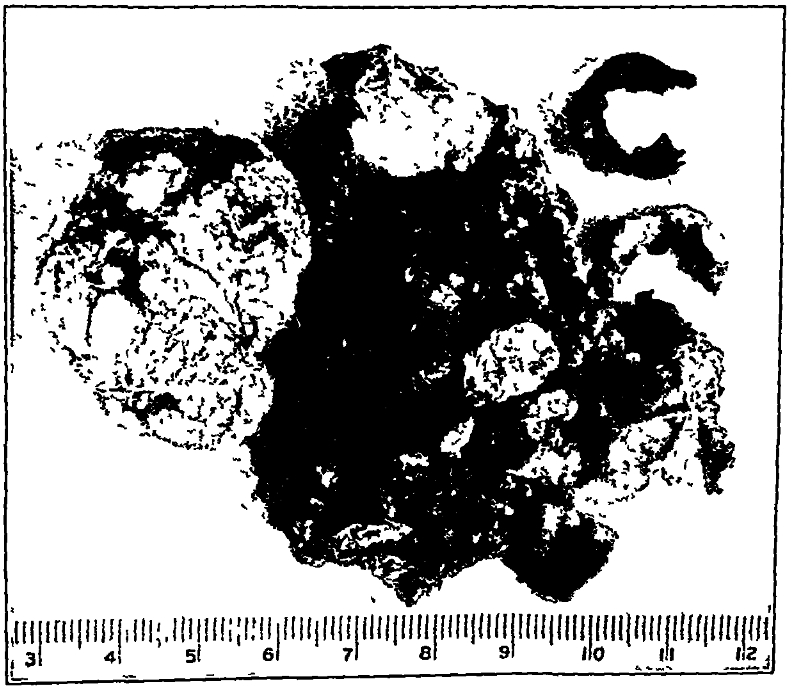
FIGS 22 AND 23

Case 2 The patient three weeks after operation, to show the situation of the nearly invisible frontal scar

To those surgeons who may be accustomed to speed up their operations this may appear to have been an unnecessarily prolonged and formidable procedure All said and done, it is the final result that counts, and having been brought up to believe that convalescence is shortened by attention to the technical details while the patient is on the operating table, I have no dread of a long session However, though an operation so difficult as this will always be time-consuming, experience may serve to shorten it In the other patient I have mentioned as having entered the hospital coincidentally, the procedure was easier and the operation was completed in five hours without the necessity of a transfusion The growth proved to be smaller and the fragments of charred tissue weighed only 35 5 g However, in still a third case, a much larger olfactory-groove meningioma has more recently been successfully attacked by the same methods and fully nine hours were expended, an exhausting business for the surgeon and his staff, no less than for the patient

But the point to be emphasised is that these operations were all carried through at a single session with preservation of the bone-flap instead of in multiple sessions as in the case done by the old methods reported for the purpose of contrast Enough has been said to indicate that by this new method we have at our command a device which makes it possible to extirpate tumours hitherto inaccessible, the attempted removal of which would have been regarded as foolhardy in the extreme

FIG 24



Case 2 To show (on the right) the mound of tissue fragments excavated from the centre of the tumour, together with the main mural mass subsequently dislodged The large intact nodule (on the left) represents the mass which lay to the left of the midline (Natural size) Weight 60 5 g

There is unquestionably much for us to learn about the various currents suitable for dehydration, coagulation, and incision when dealing with intracranial tumours other than the meningiomas. A discussion of the subject in these its broader aspects would lead me from the main purpose of this address, which is to describe that special type of meningioma which arises from the olfactory groove. For these tumours are, to-day, not only capable of clinical recognition owing to their peculiar syndrome, but are capable of removal in a single session by this novel method of electro-surgical excavation.

Surgery, from the days when Peter Lowe here in Glasgow very probably thought the art had reached its highest development, to the time of Macewen, has progressed so rapidly that one generation would hardly recognise in the work done by the next anything more than traces of its own methods. Where do our chief obligations, as surgeons, lie? Without Humphry Davy and the discovery of the principle of inhalation anæsthesia, without Helmholtz and the ophthalmoscope, without Roentgen and the X ray, without Faraday and the alternating current, without Pasteur and his studies of fermentation, without Kelvin and thermo-dynamics, without a host of others and their discoveries, such a procedure as I have described would, in the yesterday of surgery, hardly have been dreamed of, and who can possibly foretell what the morrow may bring forth through the application of discoveries in science which may transform overnight this art of ours in way unanticipated.

The surgeon is not likely to be one to make the underlying contribution, but his practical mind leads him to experiment with it and put it to use, and the result may be revolutionising. Such was the outcome of Lister's labours while connected with your University, and Macewen who succeeded him, found surgery so broadened in scope because of its greater safety, that specialisation has come to signalise our guild. Macewen himself may well be regarded as one of the forerunners of the newest of special fields, that relating to the surgery of the nervous system.

In this field of neuro-surgery a technique utterly different from that which is usually employed by the general surgeon is essential for success, and one promising addition to this technique which is unquestionably capable of enormous development I have ventured to describe at this time. I can realise how delighted my particular teachers Theodor Kocher and W. S. Halsted, men who laid such stress on the importance of painstaking hæmostasis in surgical work, would have been, to have seen some of the new surgery which is as bloodless compared to the surgical methods they perfected, as theirs was bloodless compared to that of their contemporaries and predecessors.

Electro-surgery at least permits us to-day to remove certain brain tumours from situations and under circumstances which a year ago—indeed, six months ago—I would not have thought possible. In illustration of this I have described a single operation upon one patient and have contrasted it with the trials and tribulations of a series of operations conducted only three years ago on another patient for a similar lesion. The electro-physical principles involved are highly technical and are hardly as yet in more than an experimental stage. It will take a combination of physicist and surgeon and electrical technician working together to perfect the apparatus and to develop its future possibilities for surgery in general. Could such a triumvirate, for example, as Kelvin, whose undergraduate publication was on the "Uniform Motion of Heat in Homogeneous Solid Bodies, and its Connexion with the Mathematical Theory of Electricity"—could a Kelvin, I say, in combination with a Macewen and a re-born James Watt as their technical assistant, be resurrected to put their fertile minds and dextrous hands to the problems involved, a second revolution in surgical technique, no less startling and significant than that we owe to Lister, might well enough take place.

A CONTRIBUTION TO THE CLINICAL RECOGNITION OF PITUITARY TUMOURS

BY DR OSKAR HIRSCH,
PRIVAT-DOZENT IN THE UNIVERSITY OF VIENNA

NOT all the syndromes caused by tumours of the hypophysis are mentioned in the publications of investigators—even of those who are thoroughly acquainted with endocrine disorders—and the diagnosis of the pituitary affections is thereby rendered difficult. Most authors discuss only the acromegalic and adiposogenital types of disease due to tumours of the hypophysis, and the ocular type which I described many years ago is not mentioned. For this reason it may be useful to give a description of this type, based on experience of about 100 cases of verified hypophyseal tumours upon which I have operated. I propose also to offer some observations on acromegaly.

The Ocular Type

At the time when I described[1] this type of disease acromegaly and adiposity were the only known characteristics of pituitary tumours. The ocular type is characterised by visual disturbances without any striking constitutional disturbance. This means that the patients show no characteristic change in their appearance; the hands and feet are normal in shape, and except for pallor, which is often observed, the face does not show signs of alteration; nor is there any adiposity. On inquiry, however, the patients will nearly always say that there has been some disorder in the function of the genital glands, such as impotence or amenorrhœa. On careful examination it is generally possible to find signs which accompany tumours of the hypophysis—e. g., loss of the beard or of axillary and pubic hair, disturbance of the sweat-secretion, somnolence, mental indifference, and low body temperature. In women it is often found that milk can be expressed from the breasts.

The most important part of this syndrome is the visual disturbance. As in the other syndromes caused by pituitary tumours, this reveals itself in a diminution of the visual acuity and field. The latter appears most often in the form of bitemporal hemianopsia, and this must be looked upon as almost pathognomonic of hypophyseal tumours. (I say "almost" because I once saw it in a case of hydrocephalus.) The bitemporal hemianopsia corresponds to a certain stage of compression of the chiasma by a tumour of the hypophysis, and at other stages this form of visual defect either may not have been reached or may have been already passed and thus obscured. In lesser degrees of compression of the chiasma the bitemporal hemianopsia may exist for colours only with normal borderlines for white and with normal visual power, whereas high degrees of compression will manifest themselves in the fact that remnants of the temporal field of vision persist on one or both sides, or in amaurosis of one or both eyes.

In the *Zeitschrift für Augenheilkunde* (1921) I described the ocular symptoms in my own cases of pituitary tumours in which the diagnosis had been verified by my operation. This was the first review of its kind, for the papers of Uhthoff and Frankl-Hochwart on ocular symptoms were based on cases dating from a time when the ophthalmoscope was not yet known and examination of the fundus was impossible. In my series it was found that temporal or bitemporal hemianopsia occurred in 84 per cent. of the cases, the remaining ocular symptoms being central scotoma, homonymous hemianopsia, nasal hemianopsia of one eye and some atypical disturbances of the visual field. Primary atrophy of the optic nerves was found as often as the temporal hemianopsia (89 per cent. of cases) and in equally characteristic form Uhthoff estimates the incidence of primary atrophy at 22 per cent , and on this point the difference is seen between my series of cases examined with the ophthalmoscope and a series in which the diagnosis was often made before the instrument was invented

---

[1] Arch. f. Laryngol., 1911, No. 3, xxvi. Handb. d. ob. Luftwege, by Katz and Blumenfeld, vol. iii., p. 600.

The ocular signs seen in my other cases (about 11 per cent) were choked disc and optic neuritis So rarely have I found these affections that it seems advisable to be cautious in diagnosing pituitary tumour when choked disc and neuritis are present *In my opinion the presence of these conditions, and* particularly of neuritis, is against the diagnosis of hypophyseal tumour, and I only abandon this attitude of reserve when all the other indications—X ray, genital disturbances, trophic disorders, and appearance of the patient—leave no doubt about the presence of a pituitary tumour The series of errors in diagnosis which I described in 1921 proves how rare it is for choked disc to occur with these growths In this series the diagnosis of pituitary tumour had been made principally because radiography showed enlargement of the *sella turcica*, enlargement of which being still regarded at that time as characteristic of pituitary tumours, and in almost all the cases of error it was noted that there were choked discs These faulty diagnoses belong to the first years of my work in the territory of hypophyseal surgery, when I did not possess experience in the recognition of pituitary tumours, and since I have stuck to the rule mentioned above, about choked disc, I have not had any errors in diagnosis The reason why (with a few exceptions) only primary atrophy of the optic nerves is produced by pituitary tumours is that the tumour leads to constriction of the optic nerves by the arterial circle of Willis, and this barrier prevents the cerebro-spinal fluid from penetrating the sheaths of the optic nerves

However frequent pathological changes may be in the fundus of the eye as a result of pituitary tumours I must emphasise the fact that there are cases of tumour in which the fundus is normal, especially when the disease is not of long duration In such a case the constriction is occurring far back, and a longer time elapses before the visible changes on the papilla conform to the visual disturbances

Two Forms of Acromegaly

Acromegaly was the first pituitary syndrome to be recognised and was described by Pierre Marie in 1886 in the *Revue de Médecine* Since that time acromegaly has been considered a uniform syndrome of disease, but in my opinion it is not I have observed more than 30 cases of acromegaly and should like to divide *them into two groups*—viz (*a*) *benign (or classical)* acromegaly, (*b*) malignant acromegaly From the point of view of morbid anatomy the criterion in these two groups is the benign or malignant tumour of the hypophysis The clinical criterion is visual disturbance, which never occurs in the benign form In the malignant form the ocular troubles appear either simultaneously with the developing acromegaly or after a longer or shorter interval which may cover several years They are nearly always progressive The two forms are found in about an equal number of cases

It is not, however, the presence or absence of visual disturbance that characterises the malignant and benign forms of acromegaly, for this sign merely tells us what kind of tumour we have to deal with Visual disturbances are caused only by a tumour growing *out of the pituitary fossa* beyond the level of the cranial base, and here I must say a word about the anatomical relations of the optic chiasma to the pituitary fossa The chiasma is not situated—as many still suppose—closely in front of the pituitary fossa in the sulcus chiasmatis but is more than one centimetre *above and behind* this sulcus The space between is occupied by the cisterna chiasmatis in such a way that the chiasma itself is suspended in the cerebro-spinal fluid (Zander) As long as the pituitary tumour is growing merely towards the sphenoidal sinus and does not pass the level of the base of skull there will be no visual disturbance If, however, it has a tendency to grow also towards the base of brain it will meet with the optic chiasma, upon which the arterial circle of Willis is superimposed It will then cause visual disturbance by compressing the chiasma against the circulus vascularis (Ludwig, Turck) The progressive growth of the tumour reveals itself also in the progress of the visual disturbances

Benign Acromegaly.

As I have mentioned above, the benign type of *acromegaly, throughout its whole course is never* accompanied by visual disturbance It is caused by a tumour developing mainly within the pituitary fossa and thereby widening it more and more towards the sphenoidal sinus But this tumour has not the tendency to grow upwards towards the base of brain, it remains in a stationary condition Therefore the chiasma is not compressed, and there is no visual disturbance Besides this negative symptom the benign type of acromegaly has also some positive clinical characteristics Not always, but very frequently, *it is associated* with hypertrichosis of high degree In men we see an unusually rich growth of hair over the whole trunk, the limbs, and the buttocks In women there is a rather well-developed moustache and beard, by far surpassing the climacteric form There is much hair on the linea alba, and the growth of hair in these patients is of an almost male type

It is a striking fact that in the benign form of acromegaly genital disturbances do not occur so regularly as in the malignant form and in all the other types of disease of the hypophysis, in the benign form of acromegaly it is fairly common to females with regular or only slightly altered menses, and males with scarcely disturbed or well-preserved potency. One patient of this type married some years after the acromegaly developed, and begot several children

The changes observed in this form of acromegaly pertain especially to those parts of the body which are derived from the ectoderm These parts of the body are affected in other syndromes, too, but never in such a complete and pronounced way as in this type of acromegaly Thus we find, beside the hypertrichosis, an influence on the sebaceous and sweat-glands (numerous comedones, excessive sweating) thickening of skin with corrugation, hypertrophy of the lingual epithelium (besides the enlargement of the tongue itself), striking defects of the dental enamel and disturbances in the growth of nails, and in one case I saw a premature bilateral cataract in a woman of 47 in whose family cataract had never occurred

These patients frequently complain of violent headaches—not during the whole course of the disease, but at least in the first years and during exacerbations Since in cases of large pituitary tumour there may be no headache at all, or it may be only slight, I cannot help believing that the symptom is not the result of space in the cranial cavity being reduced by the tumour—which in benign acromegaly does not extend into the cranial cavity—but is rather a consequence of the endocrine derangement This is the most probable explanation, for the headache promptly disappears after the operation The symptom may be a consequence of swelling of the brain or thickening of the cranium

The acromegalic deformities in both types benign and malignant, are the source of serious mental upset, partly owing to disfigurement and partly because speech is impeded by enlargement of the tongue The benign form of acromegaly ought therefore to be regarded as a serious disease though there are no visual disturbances and only a benign tumour which does not give rise to transformations within the cranial cavity

The pathological lesion of benign acromegaly is a benign adenoma in the anterior lobe of the hypophysis and consists mainly of eosinophil cells From this adenoma emanates a kind of secretion, though it may not be the same secretion as that which comes from the normal anterior lobe of pituitary body, and thus we may have to deal with a hypersecretion in acromegaly But it has not yet been decided whether the normal pituitary secretion is increased, and if so, whether it is transformed as well. Although an adenoma causing benign acromegaly may have become stationary, one or other of the acromegalic features may progress so long as the adenoma continues to produce a secretion, as it may, for several years. That a tumour is stationary is indicated by the absence of visual disturbances, coupled with an increase in some of the acromegalic symptoms. Genuine diabetes mellitus is observed only in a small number of cases; more frequently there is a reduced tolerance for carbohydrates (alimentary glycosuria).

I have operated on only three patients belonging to this group, because until recently I followed the rule laid down by J. Wagner-Jauregg, in whose clinic I operated on my first cases, according to which the indication for operation is above all the existence of progressive visual disturbances. In 1911 I wrote[2] that we would be able to give up this guiding principle when we could diminish the operative mortality of pituitary tumours, and after my experience of recent years I can say that, as a result of the improved technique, death after operation on the hypophysis is very rare. In the three cases of benign acromegaly in which I have operated benign tumours were found, consisting of eosinophil adenoma.

Malignant Acromegaly

I use the term malignant acromegaly because the condition is produced by a tumour which is progressively growing—i.e., a clinically malignant tumour—instead of being caused by the stationary tumour characterising benign acromegaly. I speak of a clinically malignant tumour because even by post-mortem and histological examination its malignancy is sometimes not easily proved. Unrestrained growth is no doubt observed, but it is generally expansive, and only seldom is there infiltration of the neighbouring structures by a tumour-substance. Metastases are very rare, and so far I have not met with any.

The characteristic of the malignant form of acromegaly is the visual disturbance caused by a tumour with progressive growth which not only widens the sella downwards into the sphenoidal sinus but also grows upwards towards the base of brain. The optic chiasma is lying on top of the tumour and is thus pressed against the circle of Willis. In this malignant form we find all the characteristic symptoms of acromegaly as in the benign form—viz., mask-like disfigurement of the face, thickened and projecting nose, thick and everted lower lip, spaced teeth, thickened tongue, paw-like hands, with analogous deformity of feet, kyphosis of the vertebral column, hypertrophic ribs, &c. In malignant acromegaly, unlike the benign form, the type of hair is not changed, and hypertrichosis of face as well as of trunk is rare. There are even cases in which loss of beard and axillary hair has been observed. Genital disorders are found in the malignant form (in contradistinction to the benign) as regularly as in the other syndromes caused by pituitary tumours—dystrophia adiposogenitalis, and the ocular form. The violent headache of the benign acromegaly is usually not observed in the malignant form, though the pituitary tumour is far larger.

The course of development of malignant acromegaly can be explained in the following way. Originally there is an active adenoma which during its initial stage discharges a secretion by which acromegaly is produced; later the adenoma—provided it is primarily of a malignant nature—develops in a malignant way; its quality of forming a secretion is lost, and it takes on the character of those inactive tumours found in dystrophia adiposogenitalis and in the ocular type. On histological examination the tumour is not always found to be eosinophil. We have seen that the syndrome of the malignant acromegaly consists of acromegaly and various symptoms of dystrophia adiposogenitalis or of the ocular form. Therefore we must not wonder at the addition of adiposity to this type of acromegaly. The kind of visual disturbance in malignant acromegaly is the same as that observed in the dystrophia adiposogenitalis and in the ocular type.

I have discussed here only the ocular form of pituitary disorder and the acromegalic. The following types have been recognised in the sequence indicated: 1. Acromegaly (Pierre Marie, 1886). 2. Degeneratio adiposogenitalis (Frohlich, 1901). 3. The Ocular Type (Hirsch, 1911). 4. Pituitary cachexia (Simmonds, 1914). 5. Diabetes insipidus pituitaria (Simmonds, 1914). 6. Nanosomia pituitaria (Erdheim, 1916). 7. Dysostosis pituitaria (Schuller, 1921). The last is caused mainly, but not exclusively, by destruction of the hypophysis, thus resembling Falta's multiple sclerosis of the endocrine glands.

SUPPURATIVE ARTHRITIS DUE TO HÆMOPHILIC BACTERIA.

BY JOHN F. TAYLOR, M.D. CAMB.,

ASSISTANT BACTERIOLOGIST, ST. THOMAS'S HOSPITAL

A STUDY of the medical literature shows that suppurative arthritis in which organisms conforming to the *B. influenza* type have been recovered in pure culture is very unusual. It appears that since 1899 only nine cases which fulfil the above conditions have been recorded. In view of the widespread distribution of these organisms this is sufficiently remarkable. A brief record of these cases may be of interest.

Slawyk,[1] 1899: A child of 9 months with an abscess on the dorsum of the hand and arthritis of the ankle; death occurred from general infection and meningitis.

Mya,[2] 1903: A child of 1 year with purulent arthritis of shoulder-joint; meningitis, death.

Dudgeon and Adams,[3] 1907: A baby with suppurative arthritis of left elbow and right hip-joints; meningitis, death.

Fraser,[4] 1911: A child of six months, suppurative arthritis of knee. Joint opened and drained; complete recovery.

Nabarro and Stallman,[5] 1924: Three cases of purulent arthritis of the knee in children aged 1 year, 11 months, and 8 months respectively. In one of these cases the joint infection was preceded by a "cold" and pneumonia; the patient died from meningitis. The other two patients had no preceding or following complications and recovered.

Harris,[6] 1925, analysed a series of 51 cases of acute suppurative arthritis occurring in the six years 1918–1924 in the Hospital for Sick Children, Toronto. Two cases were caused by *B. influenzæ*; both were said to be hæmatogenous infections, in one the primary focus was cellulitis of the orbit. No further details are given beyond the fact that in both cases the joints recovered completely.

Maitland and Cameron,[7] evidently examined the organism from one of these cases. They refer to the strain as one from the knee-joint and blood stream of a child under Dr. Erb, in the Hospital for Sick Children, Toronto.

During the past year the following three cases have come under my notice at St. Thomas's Hospital, and the rarity of the condition seems to justify their publication.

Clinical Records

CASE 1.—M. S., female, aged 7 months. Admitted under Mr. C. M. Page with an acute arthritis of the right hip-joint. No history of preceding illness. Temp., 100°–103° F.; pulse, 100–140. The joint was incised by Mr. C. V. Patrick, resident assistant surgeon, and about 2½ oz. of thick, viscous, yellow pus evacuated. Some caries of the head of the femur and the acetabulum was noted. The temperature and pulse fell to normal within a few days. Healing of the wound was somewhat slow, but complete after six to eight weeks. The destruction of bone produced a tendency to upward dislocation which was eventually overcome by means of plaster splinting and extension. When last seen (four months after operation) the patient's condition was in every way satisfactory.

Films of the pus, when stained by Gram's method and counterstained by dilute carbol-fuchsin, showed a moderate number of minute Gram-negative rods. Cultures on nutrient agar and in beef broth were sterile, on blood-agar a very few minute, non-hæmolytic colonies appeared, but on hæmoglobin agar the growth was profuse (This medium was prepared by adding 4 per cent of whole oxalated human blood to melted agar and heating at 80° C for five minutes) The colonies varied in size from those barely distinguishable with a hand lens up to a small pin's head, but all were discrete, regular, faintly grey in colour, and translucent No other organisms were present Films from the cultures showed marked pleomorphism A fair number of fine rods were still seen, but minute cocco-bacilli predominated and coarser rods and a few filamentous forms were also present After the third subculture the organism died Swabs from the patient's nasopharynx gave an identical organism, not in pure culture Three days after the operation the patient's serum was tested for agglutinating properties Emulsions of the organisms from the pus and nasopharynx were agglutinated in a dilution of 1 in 200 Controls with three normal sera and with saline were completely negative in all dilutions from 1 in 25 upwards

Pathogenicity —Saline emulsions were made from 24-hour subcultures on hæmoglobin-agar and doses estimated by Brown and Kirwan's method [8] A guinea-pig received 200 million bacilli intraperitoneally and two rabbits were given intravenous injections of 200 and 1000 million respectively None of these animals showed any signs of illness The early death of the organism prevented further experiments with fluid cultures or more massive doses

CASE 2 —R L female, aged 18 months Admitted under Sir Cuthbert Wallace She had had whooping-cough and was still coughing The left knee was swollen and very tender Temp , 102°, pulse, 110 The joint was aspirated and 4 c cm of semi-purulent fluid withdrawn Reaspiration was performed three times during the following week, and the patient was severely toxic for a fortnight or more The temperature became normal after three weeks, and recovery was then uneventful Two months later the joint was found to be normal, except for slight periarticular thickening

The bacteriological examinations in this case were carried out by Dr R J V Pulvertaft, pathologist to the units, St Thomas's Hospital, to whom I am indebted for the following information The pus obtained at all four aspirations showed a minute Gram-negative bacillus in pure culture This organism was identical both morphologically and culturally with that found in Case 1, and further resembled it in soon dying out in subculture It could not be found in the throat or nasopharynx, and blood culture was also negative

It was hoped to establish a serological relationship with *B pertussis*, but the death of the organism prevented further tests

CASE 3 —P K , female, aged 8 months Admitted under Mr Percy Sargent with a hot tender swelling of the lower part of the left thigh Temp , 102°, pulse, 152 X ray examination by Mr Geoffrey Fildes showed no bony change The swelling was incised over the inner side of the femur, no pus found Four days later the swelling had extended to the knee, the joint was opened on the inner side, and several ounces of fairly fluid yellow pus evacuated The general condition steadily improved, and the temperature reached and maintained a normal level after 10 or 12 days The operation wound was completely healed after three weeks Extension to prevent contracture was applied by means of a Balkan beam The patient was a congenital syphilitic, and while under treatment for this condition she contracted erysipelas, of which she died At the post-mortem no sign of disease was found in the affected joint Examination of the pus found at operation again showed a minute Gram-negative bacillus corresponding in morphological and cultural characters to the other two strains Further examination of the organism was prevented by an insuperable contamination by *B subtilis*

Discussion.

The 12 cases now recorded show one common feature in that the patients were *all children* Otherwise they fall into two groups (*a*) suppurative arthritis with fatal pyæmia and meningitis, (*b*) suppurative arthritis only In this group not only does the patient recover but the joint also recovers its normal condition and function Indeed, Nabarro and Stallman noted at the post-mortem on their fatal case that the infected joint showed a definite tendency towards repair So far, then, as the joints themselves are concerned the prognosis in these infections is a good one.

In this connexion it is perhaps interesting to note the relationship between the type of case and, when tested, the pathogenicity of the infecting organism to animals. (See table)

The doses employed in the animal experiments were very variable, but with this reservation in mind it is seen that the results of human and animal infection were fairly parallel The exception is Nabarro and Stallman's Case 1, in which the guinea-pig was given approximately the same dose as in their Case 2 No definite conclusions can be drawn from the small number of cases available, but they are shown for what they are worth

Author	Fatal to patient	Fatal to animals
Slawyk	Yes	Yes
Mya	„	„
Fraser	No	No *
Nabarro and Stallman 1	„	Yes
„ „ 2	„	No
„ „ 3	Yes	Yes †
Taylor 1 . ..	No	No ‡

* Fatal to a mouse when grown on staphylococcus agar only
† Guinea-pig died, but the organism was not recovered from it
‡ Comparatively small doses only used

The *question now arises as to what place in the* bacteriological nomenclature is to be given to these organisms The problem of classifying the hæmophilic bacteria has been attacked from several different angles Cohen [9] and Henry [10] found that strains isolated from cases of meningitis were more toxic to animals, and that they tended to kill more frequently by septicæmia than those isolated from the respiratory tract Cohen further stated that animals could be protected against meningeal strains by inoculation with such strains, but that respiratory strains did not so protect On these grounds he considered them to be a different species Henry also called attention to their marked pleomorphism in culture but made no definite separation

Dible [11] separated the hæmophilic bacteria found in the throat into three groups (*a*) hæmolytic; (*b*) non-hæmolytic but with a tendency to production of long leptothricoid threads; (*c*) non-hæmolytic, strictly hæmophilic, give uniform turbidity in fluid media, appear in films as minute bacilli or cocco-bacilli, produce sharply outlined lenticular colonies He considers that only group (*c*) should be called *Bacillus influenzæ* Pfeiffer

Maitland and Cameron [7] examined a very large number of strains as to agglutination and agglutinin absorption They considered that while a few strains showed common properties in these respects, the great majority only reacted with their homologous sera The strain recovered from Erb's case of arthritis differed from other strains no more than they did from each other.

Are any or all of the hæmophilic bacteria found in these cases of suppurative arthritis to be called *B influenzæ* Pfeiffer, are they variants of it, or are they one or more different species? It is interesting to read that the strain recovered from the first recorded case—Slawyk's—was examined by Pfeiffer himself Apparently he had no hesitation in accepting it as the organism which bears his name, but at that time no other hæmophilic bacteria had been described The increased pathogenicity and pleomorphism of some of the strains might lead us to class them with the meningeal strains described by Cohen and Henry Under Dible's classification some might be included in his group (*b*) on account of the formation of filaments in cultures In my Case 2 the occurrence of the arthritis during an attack of whooping-cough suggests that further examination might have shown the organism to have been *B pertussis* *B influenzæ* Pfeiffer is said to live indefinitely if frequently sub-cultured on hæmoglobin agar The strains from my Cases 1 and 2 both died after the third subculture, and Fraser had the same experience with hers

I do not think it is possible to place these organisms at all definitely, but the brief résumé of the evidence available may lead others who meet similar cases to do so It seems advisable in the present state of our knowledge to be content with the non-committal description of "hæmophilic bacteria"

My thanks are due to Sir Cuthbert Wallace, Mr Percy Sargent, and Mr. C M. Page for access to their case-notes, and to Dr. R J. V. Pulvertaft for his bacteriological findings in one of the cases

THE TREATMENT OF
IMPETIGO CONTAGIOSA BY MEANS OF ULTRA-VIOLET RAYS.

By J. B. ELLISON, M.B, B CHIR CAMB.,
HOUSE PHYSICIAN, QUEEN'S HOSPITAL FOR CHILDREN

TREATMENT by ultra-violet rays has recently become so popular that there is practically no pathological condition for which it has not been advised. It must, nevertheless, be confessed that at present evidence of the value of these rays rests more on the assertion of enthusiasts than on the demonstration of scientific investigators

Recently Roxburgh [6] has published the results of treatment of 276 cases of 54 distinct diseases with the mercury-vapour lamp He omits to give certain details of technique—for instance, the distance of the patient from the lamp, and the interval of time between each exposure—and does not allude to control cases

The present investigation has been undertaken in order to test the effect of ultra-violet light on a common superficial skin infection. In such a disease the results of treatment can be easily and accurately estimated and control cases can be easily obtained.

Impetigo contagiosa was selected as being exceedingly common and because it causes loss of very many school hours among London children, and does not always yield so readily to treatment as is commonly supposed, some cases requiring five or six weeks' treatment with the orthodox ammoniated mercury ointment before they can be discharged as fit for school A mixture of flavine and paraffin has been used now for some time at the Queen's Hospital for Children as a routine treatment and has proved very satisfactory, since it prevents the formation of crusts and necessity for their painful removal as with other forms of treatment A record of the results of this treatment is quoted below for comparison

In selecting cases the diagnosis was made on clinical grounds alone Crusting and a tendency to spread were the principal features looked for; some cases of impetiginised eczema are included in the list, the eczema revealing itself on the disappearance of the superficial impetigo. Bacteriological investigations were not made, but Balmain [1] has found in a series of cases—

Streptococci	43 times,	13 times in pure culture
Staphylococci	52 „	21 „ „ „
Diphtheroids	3 „	1 „ „ „

He states that the majority of cases were infected with both staphylococci and streptococci He also notices the superiority of flavine and paraffin to other forms of treatment

Most authors claim that impetigo can be easily cured by the application of ultra-violet rays For instance, W K and E H Russell [4] state that impetigo contagiosa can be cured by means of the air-cooled mercury-vapour lamp if the crusts are previously removed, and if a third degree erythema is produced. It may be mentioned that a third degree erythema is a severe reaction producing general coarse desquamation, and is very painful They further state that the first application prevents the lesions from spreading, and that the disease can be cured by three or four applications

Local treatment is advised at short range "For the bactericidal effect, and to increase the flow of blood and lymph to the part" They add, "we have treated a large number of children with this condition, and have been uniformly successful" Unfortunately, only one case is quoted, in which cure was effected *after four applications in a week.* It is not stated whether any local antiseptic was used in this case

Troup [5] quoted one case as cured after 12 applications Ferguson [2] suggests local treatment at 12 inches with five minutes' exposure, and says that a third degree erythema is desirable. He mentions three cases, but gives no details. Roxburgh [6] has 11 cases of impetigo in his list Of these three were cured or much improved. three were somewhat improved; there was no improvement in two cases and no report on three He remarks: "In impetigo contagiosa the cure seemed to be definitely accelerated in more than half the cases by the employment of ultra-violet light, in addition to ordinary antiseptic treatment" (he omits to define this further), "and in one or two cases to be possible with U V.L alone X rays, as is well known make impetigo worse." The kind of lamp used is not stated.

The type of lamp used appears to have an important bearing on the matter, since the nature of the rays escaping from the water-cooled variety differs from that of those which emerge from the more generally used air-cooled lamp Thus Humphris [3] states. "Near ultra-violet intensity (filtered through mercury vapour as in the air-cooled lamp) has not much germicidal action, but is more penetrative." If this be so it would be expected that the cure of impetigo by means of the air-cooled lamp would be effected rather by building up bodily resistance than by the direct germicidal action of the rays The following observations tend to confirm this view

Technique Employed in the Present Investigation.

One lamp was used for the treatment of all cases This was the Cooper Hewitt direct current air-cooled quartz mercury-vapour arc lamp

Age of Lamp —The lamp had been running for rather more than 1000 hours, and consequently the emitting power had become much less than that of a new lamp

Strength of Lamp —No attempt was made to estimate the emitting power since the units employed are purely empirical and no general standard has as yet been adopted An exposure of five minutes at one foot was sufficient to produce a brisk erythema in the majority of normal children, and in one case a burn was produced by this exposure An exposure of nine minutes at three feet was sufficient to cause definite erythema of the skin of the abdominal wall in most children All the patients treated were children of ages ranging from 6 months to 15 years

Two methods of exposure were used: 1 Local exposure of the affected area alone (e g, face) at a range of one foot 2 General exposure of the whole body at a range of three feet After exposure in both cases a standard lotion was applied to the affected area. This consisted of a mixture of equal parts of lotio calaminæ and lotio nigra This lotion has weak curative properties, and was used alone on most of the control cases. Scabs and crusts were removed before the application of the rays.

Interval between Exposures.—This was in most cases two days, two days, three days. In a few instances daily applications were tried; the results of this method are recorded separately. After receiving treatment the patient's mother was instructed to apply the standard lotion at home, and to do so morning and evening, removing all crusts once a day.

Duration of Exposure.—1. Local cases. First exposure three minutes at one foot, increasing by two and a half minutes at each subsequent exposure. If a brisk erythema was produced the dose was reduced at the next exposure. 2. General cases. First dose 10 minutes (five minutes back and front), increasing two and a half minutes back and front at each subsequent exposure up to 25 minutes total.

Control Cases.—When possible controls were seen at the same time as the cases receiving light, but the standard lotion alone was used. Some cases are included in which the common ammoniated mercury ointment (gr. viii to the ounce) and the flavine and paraffin mixture were used (equal parts emulsified). Considerable difficulty was experienced in obtaining regular attendance of the controls. About 35 cases had to be rejected on this account. It was not possible to observe controls receiving no treatment whatever. The control cases were treated at home by the parents. Every effort was made to see that both sets obtained, so far as possible, identical treatment with the lotion. Those receiving flavine and paraffin, &c., were dressed daily at the hospital.

RECORD OF RESULTS

(A)—*Light Cases*

1. Local cases treated at one foot from lamp.

Total number	20 cases
Number observed to complete cure	15 „
Number improved but not observed to complete cure	4 „
Number not improved	1 case
Average duration for complete cure	13·5 days
Average duration of treatment for those cases improved but not cured	21 „
Maximum *number of exposures in any one case*	11
Minimum „ „ „ „	3
Average number of exposures	5·4
Number of cases in which erythema (third degree) was produced	6
Average time required for cure in these cases was	17½ days
Minimum dose necessary to produce erythema	5 mins.

In nine cases cure was effected without the production of erythema in an average time of ten days.

It would not be safe to conclude that the production of erythema is inadvisable in all cases, however, because those cases in which erythema occurred were on the whole more severe than the rest.

Complications arising during treatment and directly attributable to the effect of ultra-violet rays are:—

Purpura (vide Case 1)	1
Light burn—i.e., severe blistering	1
Vomiting and pyrexia	1
Acute eczema (serous discharge, continuing for some weeks)	1

Intensive local treatment was tried in two cases.

One case, J. C., aged 15, received ten exposures of five minutes each in 13 days. The face only was involved and cure was effected in 13 days after mercurial ointment had been tried for a week.

The other, A. T., aged 5, received 11 exposures in 14 days, at the end of which time his skin appeared to be in an irritable and eczematous condition, more troublesome than the original impetigo. The eczema was certainly caused by exposure at too frequent intervals. This case was a severe and intractable one, the disease having been present for a month before treatment was begun. The exposures never exceeded five minutes, and only slight erythema was produced.

2. Cases receiving general exposure at three feet distance from lamp. Total number of cases, 21.

Number observed to complete cure	19
Improved but not observed to complete cure	2
Unimproved	0

Three cases were suffering from eczema as well as impetigo at the beginning of their treatment. Of these two were cured.

Average duration for complete cure	12¾ days
Average number of exposures	5

Complications present when treatment was begun.

Phlyctenular conjunctivitis, 1 (this complication disappeared after 2 exposures without any local application). Eczema, 3 (two of these cases were cured after 12 exposures in 40 days (see Cases 2 and 3); the third ceased attending after one week). No definite erythema was produced in any of these cases, though in one or two instances the parents stated that they thought the patients' necks and faces seemed redder than usual for a few hours. No complications arose during treatment.

On the whole, *the cases receiving general treatment* were more severe than the local cases, the lesions being more widespread. Some improvement in the general condition of the patients was observed by the parents, the principal feature being improvement in appetite.

(B)—*Controls*

Total number	20 cases
Number cured	16 „
Number improved	4 „
Number receiving standard lotion alone	11
Cured	11
Average time required for cure	14·5 days
Number of cases receiving other treatment (ointment, &c.)	9

(Of these 5 were cured in an average of 20 days; 4 were much improved but ceased attendance after 10 days.)

A large number of cases have been treated with a mixture of flavine and paraffin, and were discharged in an average time of ten days.

Technique

The control cases were seen at the same times as the cases receiving light treatment and were dressed at the same time, receiving treatment at home in the intervals. One or two cases cleared up with extreme rapidity, whereas in others the spread of the disease was not checked. It is not at all easy to strike a fair average in these cases, as it would be fairly easy to select 20 cases which were cured in a week, and a further 20 remaining uncured at the end of a month. As far as possible cases of average severity of the same type as those receiving light were selected (vide Cases 5, 6, and 7).

COMPARISON OF RESULTS

Comparison between General and Local Treatment

The local cases required an average of 13½ days for cure as compared with 12¾ for those receiving general treatment. This result is definitely in favour of general exposure—indeed, more so than the figures indicate, since on the whole the cases receiving this form of treatment were more severe than those receiving local treatment, and should, therefore, have required a longer period for cure.

The fact that no definite erythemas were produced in the general cases seems to contradict the statement made in most of the current works on this subject that a smart reaction is necessary for the cure of impetigo. On the contrary, a third degree erythema has serious disadvantages: (1) it is very painful and often alarming to the patient; (2) a severe burn may easily be produced in sensitive subjects instead of the desired erythema; (3) the skin may be irritated and eczema may be caused; (4) complications are more liable to occur. Local treatment, whether erythema be produced or not, has the further disadvantage that the patient's general health is not likely to be benefited owing to the small area of body surface available for the absorption of the rays. (This is doubted by Eidinow.)

The advantages are: (1) the patient does not have to undress completely; (2) the time of exposures is much shorter.

Comparison between Light-treated Cases and Controls.

Average time required for cure in controls was 14 5 days for those receiving standard lotion, 20 days for those receiving mercurial ointment and 10 for those receiving flavine and paraffin On the whole it appears safe to say that ultra-violet light has some beneficial action though the results cannot be described as striking. The maximum effect was generally observed in cases treated for some time by other methods, in which improvement had apparently come to a standstill The superiority of flavine and paraffin to all other methods of treatment is quite obvious to anyone who is in the habit of treating a large number of cases of impetigo

Conclusion

1 Ultra-violet rays have slight though definite curative effect on cases of impetigo contagiosa
2 General exposure is safer and more efficient than local exposure at short range in this condition
3 The production of a third degree erythema is neither safe nor desirable

I wish to record my indebtedness to Dr Helen Mackay, the medical officer in charge of the Light Treatment Department, Queen's Hospital for Children, for her kind permission to publish these figures and for much invaluable assistance. Also I wish to thank the nursing staff for their unselfish aid in the collection of these results

Clinical and Laboratory Notes.

A NOTE ON

ULTRA-VIOLET RAYS IN THE TREATMENT OF CHRONIC ULCERATION

BY GLADYS M. WAUCHOPE M.D , M R C P LOND ,
ASSISTANT PHYSICIAN NEW SUSSEX HOSPITAL FOR WOMEN AND CHILDREN, BRIGHTON

IN view of the many conditions for which ultra-violet irradiation is used with varying success the following notes on three cases of chronic ulceration of the legs due to different causes may be of interest Improvement was obtained in difficult circumstances when other methods had failed

CASE 1 —*Chronic Varicose Ulceration* —The patient is a tall thin woman of 70 years formerly a working housekeeper and now living alone and doing her own work. She was first seen in May, 1924, when she said that for 16 years there had been an ulcer on her left ankle Twice it had healed for a short time as a result of three months' rest but it had only "scabbed over" and had remained painful. Examination showed a typical indolent varicose ulcer, measuring about ½ × ¾ in., below the external malleolus Round it was a boggy discoloured area measuring 4½ × 3½ in. and extending back to the tendo Achillis The veins of the foot and of the leg to the knee were dilated and knotted Apart from thickening of the arterial walls and a raised blood pressure (170/115 mm Hg) there was nothing of note in the general condition of the patient.

The usual methods of treatment were carried out vigorously for seven months firm strapping over dry lint relieved the pain to a great extent and was found to be the most satisfactory but the ulcer showed no signs of healing Calcium lactate was given three times a day in ten-grain doses from July till the end of August without apparent benefit Extract of parathyroid gr 1/20 with 10 gr of calcium lactate daily for a month in December produced no better result.

In January 1925 I asked Mr G Noakes to try irradiation with the tungsten arc lamp Treatment was begun on Jan. 22nd and continued twice a week till April 5th. The whole of the leg from foot to knee was exposed for two minutes on the first day, the time being increased gradually to a maximum of four minutes reached at the sixth exposure The ulcer was dressed with an ointment of zinc and boric acid and Unna s paste bandage was applied from the foot to the knee between the exposures The ulcer had completely healed on March 28th and was covered with rather thin scar tissue The skin round the scar was hard and firm with brown pigmentation There was no pain or tenderness Two more irradiations were given, and a wide elastic bandage applied During the treatment and afterwards the patient did her own housework shopping, &c., and from time to time helped to nurse a sick friend

The ulcer has now remained healed for two years In June 1926 the patient complained of a little pain and tenderness and there was slight œdema about the scar. After a few exposures to the ultra-violet rays the pain and swelling disappeared

CASE 2 *Diabetic Ulceration* —A woman of 48, a book-keeper in a shop attended the out-patient department at the New Sussex Hospital from Nov. 6th 1925, till Jan 22nd, 1926 while on a visit to Brighton She was a diabetic of the stout type (weight 14 st. 5 lb) and had been on insulin since the previous August She had a round ulcer about the size of a shilling on the sole of her foot. This had formed before any insulin was given and had not improved Acetone bodies were present in the urine when the patient was first seen so for a month she was kept under observation while the diet and insulin were regulated The ulcer was covered with a simple dressing

In December Mr. Noakes began treatment with the tungsten arc lamp The patient left Brighton after 12 exposures, and the ulcer was then filled with granulation tissue. Dr Olive Potter tells me that the treatment was continued and that the ulcer healed in a few weeks and has not recurred This patient had also varicose ulceration of the leg and there was fairly frequent glycosuria while she was under treatment.

CASE 3 *Erythema Induratum of Bazin* —A girl of 23 first attended the out-patient department in August, 1925 She stated that she had had painful swellings and ulcers on her legs since the age of 16, always worse in the summer. When first seen there were scars of healed ulcers on both legs, but there had been no fresh ulceration for two years. The Wassermann reaction was negative In October 1926 there was much general swelling of both legs which were cold and cyanosed There were many subcutaneous nodules, several being inflamed, and ulceration occurred on both legs After ten applications of ultra-violet rays, again by Mr. Noakes, the ulcers had healed the nodules disappeared, and the legs were slimmer, the patient said, than they had been for years In December there was a recurrence of ulceration in two places and again irradiation brought about rapid healing

The following points may be noted · (1) In the first case the long duration of the ulcer and the resistance to other treatment (2) In the second case the position of the ulcer on the sole of the foot, which was not kept at rest, made healing difficult Moreover, the patient was by no means sugar-free during or before treatment (3) In the third case the severe and distressing condition of the legs in a young woman and the remarkable improvement obtained.

SPLENECTOMY AND ITS COMPLICATIONS IN EGYPTIAN SPLENOMEGALY.

BY F A. SAYED M B LOND . M R C S ENG ,
PRINCIPAL MEDICAL OFFICER GOVERNMENT HOSPITAL, KALIOUB

THE hospital to which I am attached is situated ten miles north of Cairo It has an attendance of some 22 000 patients yearly at the annexe for bilharzia and ankylostome infections These patients come from Lower Egypt Most of our splenomegaly cases came from the Eastern Delta a few from the Central Delta, and none from Upper Egypt This distribution of cases may be due to proximity of hospital to the first two areas but it is significant that Coleman, of Old Cairo reports a high incidence of splenomegaly in the Eastern Delta

Splenomegaly may occur at almost any age, it is commonest between 15 and 30 years Our youngest of the control cases Scabs and crusts were removed before the application of the rays

Interval between Exposures—This was in most cases two days, two days, three days In a few instances daily applications were tried , the results of this method are recorded separately *After receiving treatment the patient's mother* was instructed to apply the standard lotion at home, and to do so morning and evening, removing all crusts once a day

Duration of Exposure—1 Local cases First exposure three minutes at one foot, increasing by two and a half minutes at each subsequent exposure If a brisk erythema was produced the dose was reduced at the next exposure 2 General cases First dose 10 minutes (five minutes back and front), increasing two and a half minutes back and front at each subsequent exposure up to 25 minutes total

Control Cases—When possible controls were seen at the same time as the cases receiving light, but the standard lotion alone was used Some cases are included in which the common ammoniated mercury ointment (gr viii to the ounce) and the flavine and paraffin mixture were used (equal parts emulsified) Considerable difficulty was experienced in obtaining regular attendance of the controls About 35 cases had to be rejected on this account It was not possible to observe controls receiving no treatment whatever The control cases were treated at home by the parents Every effort was made to see that both sets obtained, *so far as possible, identical treatment* with the lotion Those receiving flavine and paraffin, &c , were dressed daily at the hospital

RECORD OF RESULTS

(A)—*Light Cases*

1 Local cases treated at one foot from lamp

Total number	20 cases
Number observed to complete cure	15 ,,
Number improved but not observed to complete cure	4 ,,
Number not improved	1 case
Average duration for complete cure	13 5 days
Average duration of treatment for those cases improved but not cured	21 ,,
Maximum number of exposures in any one case	11
Minimum , ,, ,, ,,	3
Average number of exposures	*5 4*
Number of cases in which erythema (third degree) was produced	6
Average time required for cure in these cases was	17½ days
Minimum dose necessary to produce erythema	5 mins

In nine cases cure was effected without the production of erythema in an average time of ten days

It would not be safe to conclude that the production of erythema is inadvisable in all cases, however, because those cases in which erythema occurred were on the whole more severe than the rest

Complications arising during treatment and directly attributable to the effect of ultra-violet rays are —

Purpura (vide Case 1)	1
Light burn—i e , severe blistering	1
Vomiting and pyrexia	1
Acute eczema (serous discharge, continuing for some weeks)	1

Intensive local treatment was tried in two cases

One case, J C , aged 15, received ten exposures of five minutes each in 13 days The face only was involved and cure was effected in 13 days after mercurial ointment had been tried for a week

The other, A T , aged 5, received 11 exposures in 14 days, at the end of which time his skin *appeared to be in* an irritable and eczematous condition, more troublesome than the original impetigo The eczema was certainly caused by exposure at too frequent intervals This case was a severe and intractable one, the disease having been present for a month before treatment was begun The exposures never exceeded five minutes, and only slight erythema was produced

2 Cases receiving general exposure at three feet distance from lamp Total number of cases, 21

Number observed to complete cure	19
Improved but not observed to complete cure	2
Unimproved	0

Three cases were suffering from eczema as well as impetigo at the beginning of their treatment Of these two were cured

Average duration for complete cure	12¾ days
Average number of exposures	*5*

Complications present when treatment was begun.

Phlyctenular conjunctivitis, 1 (this complication disappeared after 2 exposures without any local application) Eczema, 3 (two of these cases were cured after 12 exposures in 40 days (see Cases 2 and 3) , the third ceased attending after one week) No definite erythema was produced in any of these cases, though in one or two instances the parents stated that they thought the patients' necks and faces seemed redder than usual for a few hours No complications arose during treatment

On the whole, the cases receiving general treatment were more severe than the local cases, the lesions being more widespread Some improvement in the general condition of the patients was observed by the parents, the principal feature being improvement in appetite.

(B)—*Controls*

Total number	20 cases
Number cured	16 ,,
Number improved	4 ,,
Number receiving standard lotion alone	11
Cured	11
Average time required for cure	14 5 days
Number of cases receiving other treatment (ointment, &c)	9

(Of these 5 were cured in an average of 20 days , 4 were much improved but ceased attendance after 10 days)

A large number of cases have been treated with a mixture of flavine and paraffin, and were discharged in an average time of ten days

Technique

The control cases were seen at the same times as the cases receiving light treatment and were dressed at the same time, receiving treatment at home in the intervals One or two cases cleared up with extreme rapidity, whereas in others the spread of the disease was not checked It is not at all easy to strike a fair average in these cases, as it would be fairly easy *to select* 20 *cases* which were *cured* in *a* week, and a further 20 remaining uncured at the end of a month As far as possible cases of average severity of the same type as those receiving light were selected (vide Cases 5, 6, and 7)

COMPARISON OF RESULTS

Comparison between General and Local Treatment

The local cases required an average of 13½ days for cure as compared with 12¾ for those receiving general treatment This result is definitely in favour of general exposure—indeed, more so than the figures indicate, since on the whole the cases receiving this form of treatment were more severe than those receiving local treatment, and should, therefore have required a longer period for cure

The fact that no definite erythemas were produced in *the general cases seems to contradict* the statement made in most of the current works on this subject that a smart reaction is necessary for the cure of impetigo On the contrary, a third degree erythema has serious disadvantages (1) it is very painful and often alarming to the patient , (2) a severe burn *may easily be produced* in sensitive subjects instead of the desired erythema , (3) the skin may be irritated and eczema may be caused , (4) complications are more liable to occur Local treatment, whether erythema be produced or not, has the further disadvantage that the patient's general health is not likely to be benefited owing to the small area of body surface available for the absorption of the rays (This is doubted by Eidinow)

The advantages are (1) the patient does not have to undress completely , (2) the time of exposures is much shorter.

etherised and the control flies Two types of flies were used, the ordinary wild type of drosophila, and the smaller vestigial type with rudimentary wings that was discovered in Morgan's laboratory.

Prof. Pearl laid stress on the great difficulty of biological experiments, as they involved psychology and behaviourism as well as physiology, long study was needed from many points of view before an experiment could be properly set up Much of the apparently greater variability of biological phenomena as compared to those of physics and chemistry was due to general sloppiness in experimental method To describe his results, he showed age survivorship tables starting from the emergence of the *imago, and excluding the larval and pupal stages* These tables were smoothed by the formula log $l_x = e^x(a+bx+cx^2+dx^3)$, but in actual fact the coefficients *of the two last terms* were almost negligible The chief points of interest were (1) the general resemblance of form to that part of the human survivorship curve from 12 years of age onward, (2) that the same relation between the sexes held as in human life, the female having in each case a greater hold on life, (3) that the curve for the vestigial type differed in form from that of the wild type, the vestigial curve approximating to that of a constant death-rate in middle life, and (4) that the expectation of life was of the same order in days as that of man in years

In order to superimpose the human and fly survivorship curves in comparable time units, the question arose what point in human life corresponded to the point of emergence of the fly? The two most logical points to make *coincident appeared to* be those at which only one survivor would be left out of one thousand births, and at the other end of the scale the points at which the instantaneous death-rate q_x was a minimum—i e, one day of age for drosophila and 12 years of age for man (using the U S A life tables) When centiles of equivalent life span were taken as time units for age, the survivorship curves of man and the wild type of fruit fly followed each other well, but that of the vestigial type of fly fell considerably below The main points of interest from this comparison were (1) That the distribution of mortality in different parts of the life span, taking biological age as the base, was essentially the same in the wild fruit fly as in man, this quantitative resemblance did not, of course, imply a qualitative resemblance of cause, but did suggest some underlying factor of importance of which age was one expression (2) That the genetic change from the wild type to the vestigial type involved a profound change in the distribution of mortality. There were two limiting types of survivorship curve, the one approaching the rectangular form corresponding to a very light mortality throughout the greater part of life and a very high death-rate at the latter end, which in its most extreme form would correspond to a single day of judgment for all The wild fruit fly tended towards this type The other was a diagonal survivorship curve corresponding to a constant force of mortality at all ages The vestigial type was nearer to this form. Between these theoretical extremes most life curves lay A third extreme form —also rectangular—was theoretically possible, and would result from a very heavy selective early mortality followed by a fairly constant light rate, but it was difficult to see how this could occur These observations raised the question of the biological explanation of the remarkable difference in the life duration distribution between the wild and vestigial type of drosophila.

The Second Lecture

On June 9th Prof Pearl described further experiments on drosophila designed to elucidate the factors influencing the marked differences in mortality already referred to Food was the first environmental factor studied, the excess mortality on the banana medium over that on the synthetic medium had already been noted, but it was found that unless food variations were grossly outside the normal no startling differences in mortality occurred Density of population in the bottle, however, had early proved itself to be an environmental factor of weight, and series of experiments had followed up this point The first series involved 15,000 normal wild flies, the food used was the banana medium, and the flies were kept at 25° C in 530 1 oz phials at 20 different densities varying from 2 to 200 flies per bottle All bottles were of the same size with the same amount of food (5 c cm) in each *It* was found that an initial density of 35 flies per bottle was the optimum, higher and lower densities both gave higher mortality The age-specific death-rate curves, when plotted against different initial densities, tended to become flatter as age increased The mean duration of life rose steeply as the initial density rose from 2 to 15, then more slowly, remaining almost horizontal, till a density of about 55 was reached, after which the mean duration of life declined steadily till the initial density was about 200 For higher densities the decline in mean duration was very gradual The main results were. (1) That the rate of mortality was profoundly influenced by the density of the population when the latter was confined in a limited space, the volume and surface of the food-supply being constant for all densities, (2) that the optimal initial density was about 35 to 55 flies per 1 oz bottle, and (3) that the deleterious effect of higher or lower densities was most pronounced in the first few days of imaginal life Prof. Pearl said that these results had been many times confirmed, and that the same characteristics appeared with the new synthetic food medium as with the banana medium

The effect of sudden large changes in population density was then tried Bottles at initial densities of 35 and 200 flies were started, some of these were used as controls; in others the population, which had started at an initial density of 200, was on the sixteenth day again made up to 200 by adding 16 day old survivors from bottles of initial density (*a*) of 35, and (*b*) of 200 The newcomers were distinguished from the old inhabitants by slight wing-tip clipping The results showed that while the mean duration of life of flies in a control bottle with initial density 35 was about double that of flies in a control bottle with initial density 200, those flies which had spent the first 15 days of their life in the bottle of initial density 35 had their further expected duration of life decreased by transfer to a density of 200, and that those which had spent their first 15 days in a bottle of initial density 200 and were transferred to a density of 200 again on their sixteenth day showed a still higher subsequent mortality, higher also than the controls in a bottle of initial density 200 left to die out without further additions Hence crowding in early life had deleteriously affected the survivors, and also crowding as late as the sixteenth day increased the subsequent mortality An unexpected feature was that a minimal density was not an optimum Density could not, however, explain the differences between the wild and vestigial types

Further experiments on the *inheritance* of duration of life had proved (1) that genetic differences affected the duration of life, (2) that those differences were capable of isolation by selection and inbreeding, and (3) that they remained constant over a period covering 10 to 25 generations The experiments were as follows Pairs of virgin brothers and sisters had been mated and their progeny allowed to mate at random each within its own line only The different lines showed marked differences in mean duration of life The inbreeding *within the same line* had been continued for seven months and the mortality retested in the progeny of another brother and sister in each line The different lines stood in the same order *as before* as regards duration of life The interval had covered the biologically long period of 18 generations and there had been only *one* initial selection

Prof Pearl stated that these experiments had been many times repeated, *hence it was confirmed* that patient was 7 and oldest 35 Cirrhosis and ascites develop early and prevent a ripe age being reached. In 1925 we performed splenectomy in 21 cases of splenomegaly Three were females Eighteen, including the females, harboured *Bilharzia hæmatobium*, in ten the stools revealed *B mansoni* also, and in 15 ankylostome infection In three cases only was no helminth infection demonstrated

We hold the opinion that there is some relation between bilharziasis and splenomegaly, for the following reasons (1) Higher incidence of bilharziasis and splenomegaly in males than in females (2) Demonstration of bilharzia in almost every case of splenomegaly (3) Portal bilharzial cirrhosis is reported from every case of splenomegaly where liver has been examined after death (4) Calcified bilharzia ova are found in nearly all the spleens removed and treated with 5 per cent NaOH (5) *B mansoni* and splenomegaly are found far more often in Lower than in Upper Egypt (6) In *Schistosoma japonicum* infections a picture very like to that found in Egypt is reported—viz , enlarged spleen, cirrhosed liver ascites

Operation

An injection of pneumococcal vaccine (50 million) was given five days before, and an injection of morphia and atropine half an hour before, operation Chloroform was used, for the hospital attendant who acted as anæsthetist could give nothing else High stovaine was tried twice, but not again, because both patients fainted when spleen was drawn out of abdomen In each case the incision was a median, and a transverse right through abdominal muscles to the ribs, affording full view of spleen and its bed Adhesions could thereby be separated under direct observation and the pedicle easily got at The freed spleen was brought out of the abdomen, turned over to the patient's right, thus exposing posterior surface of pedicle, and by gentle gauze dissection the tail of the pancreas was separated and splenic vessels isolated and ligatured in two places Omentum, usually adherent to pedicle, was separated Both sides of broad pedicle were clamped as close to spleen as possible, and the spleen removed It was found that dealing in this way with pedicle (from back, not from front) made it an easy operation, sometimes completed in 20 minutes In two cases good results followed reinjection into patient of the splenic blood (1 to 2 kg) previously treated with 5 per cent sod cit solution This was not more often done because the patients were as a rule in good condition on leaving the operation table It is an easy and ready method of treating cases suffering from shock, or much loss of blood, from this operation The spleens removed weighed from 0 8 to 2 5 kg

Blood counts before operation gave averages of 3 to 4 million red, 3 to 6 thousand white, cells with large and small lymphocytes and eosinophiles slightly increased One girl before operation showed a leucopenia of 1500 white cells —she made a good recovery Although ascites rather forbids operation, two cases, after one tapping and the fluid very slow in returning, made good after-operation recoveries

Complications after Operation.

There were two cases of pneumonia with recovery Two cases of right hemiplegia occurring on the seventh and eighth day respectively recovered with slight spasticity of leg

Deaths Two patients died suddenly on seventh and tenth day respectively from pulmonary embolism One case of double broncho-pneumonia was fatal on thirty-second day One patient on the ninth day developed tenderness in the right hypochondrium, vomiting, diarrhœa, melæna, and ascites Death occurred seven days later, and examination revealed embolism of a small branch of the superior mesenteric vein with œdema, congestion, and chocolate-like colour of two feet of small intestine, and local peritonitis Thus embolism, cerebral, pulmonary, abdominal, occurred in five cases It is perhaps the cause of the pneumonia that may set in with dramatic suddenness soon after operation

Most of the 17 survivors were seen from four to eight months later They were then in good health and at work Without operation all would have died within two or three years High as is the mortality after the operation, yet splenectomy to-day holds out the only hope in these cases of avoiding an early death

EXPERIMENTAL VITAL STATISTICS.

PROF RAYMOND PEARL'S LECTURES.

THREE lectures on experimental vital statistics were recently given at University College by Prof Raymond Pearl, Director of the Institute for Biological Research at the Johns Hopkins University, Baltimore The chairman at the first lecture was Sir George Buchanan, senior medical officer of the Ministry of Health, who referred to the wide range of subjects with which public health workers in practical applied epidemiology now came into touch From the original starting-point of medicine the field in earlier years was mainly confined to engineering and analytical chemistry, but now entomology, biochemistry, zoology, and many other subjects were involved, and behind all these lay the art or science of the statistician Prof Pearl had the medical knowledge and the practical training necessary to interpret his work as an epidemiologist and as a statistician

Prof Pearl expressed his pleasure at being again at University College, to which he had come 22 years ago as a student under Prof Karl Pearson, from whom he had received inspiration for his work

The First Lecture

His subject to-day, he said, was not epidemiology but an attempt to develop part of the field of biology not hitherto much discussed The work of the vital statistician covered important problems of biology It was impossible to discuss organic evolution without studying birth- and death-rates His thesis was that biostatistics was not simply the handmaiden to preventive medicine, but a symbol of the *biology of groups* The whole was different from and greater than its parts " Holism " and emergent evolution were brought to the fore by the work of Lloyd Morgan, Smuts, Henderson, Jennings, and others who recognised that the group had attributes peculiar to itself which needed measurement as much as those of the individual Statistical technique was the only means available for discussing the attributes of groups, the usual methods of description in biology were fundamentally incapable of giving a description of the group except in terms of the individual

As in the general methodology of science experiment had its part, so also it had its part in group biology The experimental biostatistics to be described had been carried out in his laboratory at the Johns Hopkins University over a period of eight years In choice of animals for such work it was essential (1) that they should be short lived, (2) that they should breed freely in captivity, (3) that their husbandry in the laboratory should be simple Mice had been used at first, but at the end of the first year a calamity had destroyed the whole colony in a single half hour Since 1919 the fruit fly *Drosophila melanogaster* had been exclusively used, and had proved completely satisfactory for a study of the forces of mortality and natality

After a brief summary of the somewhat scanty previous work done on this subject on other animals than man, Prof Pearl described the life-history of the fruit fly and the technique used in his experiments The life-cycle was short, 9–11 days covering the period from egg to egg The flies were bred in glass bottles with a food substratum at the bottom A synthetic food of salts and sugar, solidified with agar and with yeast growing on the surface, had been found more satisfactory and less variable than the cooked banana pulp used at first It was sterile by virtue of its high acidity, and experiment had proved that not only did the synthetic food increase the birth-rate, but that the mortality was three times greater on the banana medium than on the synthetic medium Immediately after emergence from the pupal stage the flies were lightly etherised for the purpose of sex determination Tests showed no marked difference between the duration of life of the etherised and the control flies Two types of flies were used, the ordinary wild type of drosophila, and the smaller vestigial type with rudimentary wings that was discovered in Morgan's laboratory.

Prof Pearl laid stress on the great difficulty of biological experiments, as they involved psychology and behaviourism as well as physiology, long study was needed from many points of view before an experiment could be properly set up Much of the apparently greater variability of biological phenomena as compared to those of physics and chemistry was due to general sloppiness in experimental method To describe his results, he showed age survivorship tables starting from the emergence of the imago, and excluding the larval and pupal stages These tables were smoothed by the formula log $l_x=e^x(a+bx+cx^2+dx^3)$, but in actual fact the coefficients of the two last terms were almost negligible The chief points of interest were · (1) the general resemblance of form to that part of the human survivorship curve from 12 years of age onward, (2) that the same relation between the sexes held as in human life, the female having in each case a greater hold on life, (3) that the curve for the vestigial type differed in form from that of the wild type, the vestigial curve approximating to that of a constant death-rate in middle life; and (4) that the expectation of life was of the same order in days as that of man in years

In order to superimpose the human and fly survivorship curves in comparable time units, the question arose what point in human life corresponded to the point of emergence of the fly? The two most logical points to make coincident appeared to be those at which only one survivor would be left out of one thousand births, and at the other end of the scale the points at which the instantaneous death-rate q_x was a minimum—i e, one day of age for drosophila and 12 years of age for man (using the U S A life tables) When centiles of equivalent life span were taken as time units for age, the survivorship curves of man and the wild type of fruit fly followed each other well, but that of the vestigial type of fly fell considerably below The main points of interest from this comparison were (1) That the distribution of mortality in different parts of the life span, taking biological age as the base, was essentially the same in the wild fruit fly as in man, this quantitative resemblance did not, of course, imply a qualitative resemblance of cause, but did suggest some underlying factor of importance of which age was one expression (2) That the genetic change from the wild type to the vestigial type involved a profound change in the distribution of mortality. There were two limiting types of survivorship curve, the one approaching the rectangular form corresponding to a very light mortality throughout the greater part of life and a very high death-rate at the latter end, which in its most extreme form would correspond to a single day of judgment for all The wild fruit fly tended towards this type The other was a diagonal survivorship curve corresponding to a constant force of mortality at all ages The vestigial type was nearer to this form. Between these theoretical extremes most life curves lay A third extreme form —also rectangular—was theoretically possible, and would result from a very heavy selective early mortality followed by a fairly constant light rate, but it was difficult to see how this could occur These observations raised the question of the biological explanation of the remarkable difference in the life duration distribution between the wild and vestigial type of drosophila

The Second Lecture

On June 9th Prof Pearl described further experiments on drosophila designed to elucidate the factors influencing the marked differences in mortality already referred to Food was the first environmental factor studied, the excess mortality on the banana medium over that on the synthetic medium had already been noted, but it was found that unless food variations were grossly outside the normal no startling differences in mortality occurred Density of population in the bottle, however, had early proved itself to be an environmental factor of weight, and series of experiments had followed up this point The first series involved 15,000 normal wild flies, the food used was the banana medium, and the flies were kept at 25° C in 530 1 oz phials at 20 different densities varying from 2 to 200 flies per bottle All bottles were of the same size with the same amount of food (5 c cm) in each It was found that an initial density of 35 flies per bottle was the optimum, higher and lower densities both gave higher mortality The age-specific death-rate curves, when plotted against different initial densities, tended to become flatter as age increased. The mean duration of life rose steeply as the initial density rose from 2 to 15, then more slowly, remaining almost horizontal, till a density of about 55 was reached, after which the mean duration of life declined steadily till the initial density was about 200 For higher densities the decline in mean duration was very gradual The main results were. (1) That the rate of mortality was profoundly influenced by the density of the population when the latter was confined in a limited space, the volume and surface of the food-supply being constant for all densities, (2) that the optimal initial density was about 35 to 55 flies per 1 oz bottle, and (3) that the deleterious effect of higher or lower densities was most pronounced in the first few days of imaginal life Prof Pearl said that these results had been many times confirmed, and that the same characteristics appeared with the new synthetic food medium as with the banana medium

The effect of sudden large changes in population density was then tried Bottles at initial densities of 35 and 200 flies were started, some of these were used as controls; in others the population, which had started at an initial density of 200, was on the sixteenth day again made up to 200 by adding 16 day old survivors from bottles of initial density (*a*) of 35, and (*b*) of 200 The newcomers were distinguished from the old inhabitants by slight wing-tip clipping The results showed that while the mean duration of life of flies in a control bottle with initial density 35 was about double that of flies in a control bottle with initial density 200, those flies which had spent the first 15 days of their life in the bottle of initial density 35 had their further expected duration of life decreased by transfer to a density of 200, and that those which had spent their first 15 days in a bottle of initial density 200 and were transferred to a density of 200 again on their sixteenth day showed a still higher subsequent mortality, higher also than the controls in a bottle of initial density 200 left to die out without further additions Hence crowding in early life had deleteriously affected the survivors, and also crowding as late as the sixteenth day increased the subsequent mortality An unexpected feature was that a minimal density was not an optimum Density could not, however, explain the differences between the wild and vestigial types

Further experiments on the inheritance of duration of life had proved (1) that genetic differences affected the duration of life, (2) that those differences were capable of isolation by selection and inbreeding, and (3) that they remained constant over a period covering 10 to 25 generations The experiments were as follows Pairs of virgin brothers and sisters had been mated and their progeny allowed to mate at random each within its own line only The different lines showed marked differences in mean duration of life. The inbreeding within the same line had been continued for seven months and the mortality retested in the progeny of another brother and sister in each line. The different lines stood in the same order as before as regards duration of life The interval had covered the biologically long period of 18 generations and there had been only *one* initial selection

Prof Pearl stated that these experiments had been many times repeated, hence it was confirmed that duration of life was—in part at least—controlled by genetic factors He continued, that when flies of the vestigial type (which had a mean duration of life only one-third that of normal wild flies) were crossed with the normal wild type the vestigial characteristics behaved as a simple Mendelian recessive character, the gene being in the sex chromosome In the first generation all were of the normal wild type, in the second the proportions of wild to vestigial had been three to one and the shorter duration of life was invariably associated with the rudimentary form of the wings of the vestigial type Tests as to the possibility of this being a purely physiological result of the handicap of inability to fly were made by clipping the wings of normal wild flies just after emergence Apart from the accidental mortality directly caused by the operation the subsequent age-specific mortality of the clipped flies did not significantly differ from that of the normal wild flies Further experiments showed that other genes besides that of the vestigial type affected the duration of life

Prof Pearl considered that the most reasonable explanation of this mass of clean-cut facts was given by assuming that duration of life was not a biologically separate character, but was an inclusive function of the organisation of the individual constitution This constitution being inherited, duration of life behaved as if it were itself inherited This view had been supported by other workers If the genetic constitution of the individual was known, and the environmental conditions were constant, then the duration of life could be predicted closely

The Third Lecture

The last lecture was given on June 10th, and Prof Pearl began it by discussing the *difficulty of* defining life The essence of life lay in dynamics not statics Vitality was a convenient term that might be defined as the intensity of vital activity and was dependent on the rate of transformation of energy If A denoted an external source of energy from non-living matter, B a living organism, and C the product—which might be (*a*) heat, (*b*) work, (*c*) the component matter of the organism, or (*d*) waste—then B might be looked on as an aggregation of matter that had the property of changing A to C by virtue of its pattern or organisation Any measurable manifestation of this transformation of energy might be taken as some sort of measure of vitality

One such measure was duration of life, and the first series of experiments to be described dealt with the total duration of life of drosophila when food was absent

Flies lately emerged were put into 1-oz phials at different densities without food The moisture conditions were carefully controlled so that there was no desiccation effect over and above starvation Dead flies were removed every six hours At density 50 the mean duration of life was about 45 hours, and when the survivorship distribution was put on a comparable scale with other results by taking as time-unit percentiles of equivalent life-spans, the distribution was found to be practically identical with that of the normal flies under ordinary conditions of feeding, hence, it appeared that in drosophila the form of the distribution of inherent vitality—i e, that depending solely on the individual pattern inherited—was the same as that depending also on environmental conditions

The growth of a seedling plant under sterile conditions in the dark and with no other food than that inherent in the cotyledons was next taken as another expression of the total organisation of the individual—i e, of B freed from A

Samples of 200 cantaloupe (*Cucumis melo*) seeds were drawn at random under the sole condition that the total weight should be constant, they were soaked for three hours, drained, placed in the incubator on agar plates, and examined at frequent intervals As soon as any seed showed signs of growth it was put on to a dish and kept in the dark at a constant temperature of 20° C The growth at the end of 48 hours was measured, and the cotyledons, stem and root parts were weighed separately to 0·1 mg

The inherent vitality could be expressed as a function of the two elements: (1) *the amount of* new substance added to the organism by growth, and (2) the time taken to accomplish the amount of growth In this case this time was fixed at 48 hours but the time taken for the seed to begin to germinate differed in different seeds and was clearly also dependent on the inherent vitality Comparison of the survival curves of starved drosophila and of the growth of the starved seedling in comparable time units showed that the form of the distribution of individual vitality, so far as it depended solely on innate constitution, was the same whether measured by growth or survival, the environmental conditions being constant for all individuals in both cases The two types of flies—normal wild and vestigial—which under normal food conditions (i e, A+B) had shown marked differences in mean length and distribution of survival were then both observed under starvation conditions (i e, B alone), and the differences in survival between the two types now disappeared The results were the same at all densities Hence it appeared *not* that the inherent vitality was altered by environmental conditions, but that the vestigial type was not able to take so much advantage of A conditions as the wild type The gene for the vestigial type had as part of its somatic expression a reduced duration of life, but under starvation conditions the differences between the two types arising from this no longer appeared owing to absence of A conditions for either

Prof Pearl next described his experiments investigating the relation of growth and survival in the *same organism* Single cantaloupe seeds were placed in long aseptic glass tubes without food and incubated in the dark at 30° C, they were examined regularly in a dark room with ruby light and the height of the stem was measured The growth of the stem followed a slightly skew form of the logistic curve described elsewhere by Prof Pearl as an expression of population growth The seedlings went through three stages (1) a period of active growth, (2) a period of suspended animation, not growing but still living, and (3) a period of death Death was a progressive process covering a number of days, and it had been found that the best point to take as end-point of life was the beginning point of death—i e., the time of the first appearance of abnormality in the stem The very definite result that emerged was a significant negative correlation between growth-rate and duration of life in the same organism of the order—0 46 ± 0 07 Prof Pearl claimed that this result gave numerical support to a suggestion made by him some years before in the "Biology of Death," that the duration of life was a function of two variables, (1) the constitution of the individual, and (2) the average metabolism or rate of energy expenditure during life If the latter were high, life would be short, and vice versa Another line of evidence that had subsequently supported this was that in man a positive relation had been found between age-specific death-rates from 40–45 on and expenditure of energy as measured by occupation, a high mortality being associated with high energy expenditure The negative correlation between rate of growth and duration of life remained unchanged when total growth and length of stem were kept constant Growth and duration of life were each only dynamic expressions of *part* of the inherent vitality These results suggested as a rational expression for total inherent vitality V, that

$$V - k_1 m_1 v_1^2 - k_2 m_2 v_2^2 - \qquad - k^n m_n v_n^2 = 0$$

where the terms such as kmv^2 represented energy expended on different things, and the k's were constants depending on the individual vital constitution There would be no great difficulty in getting V to a first approximation by making separate measurements of different expenditures of energy such as growth and metabolism, and Prof Pearl said he was doing this for seedlings Vitality was analogous to the potential energy of the charge of a Leyden jar

Summary

Prof Pearl then summed up the main results of his experiments In a single organism, the fruit fly drosophila, survivorship curves under normal food conditions were essentially different both in average duration and form, for the two different genetic types normal wild and vestigial, the environment being the same for both types Environment did have an effect on survivorship as by changing the density of the population it was possible to make the survivorship curve of the normal wild flies approximate to that of the vestigial type Under starvation conditions the differences in survivorship between the types disappeared Prof Pearl deduced that the two types possessed the same inherent vitality, which he defined as the total capacity of an organism to perform actions in the complete absence of any exogenous source of energy Hence the reason why neither density nor type produced any differences under starvation conditions was that they were both only preventive in action under normal conditions Duration of life was by no means the only expression of vitality, growth was another There was reason to expect that individual differences in inherent vitality would have the same distribution whatever expression was chosen for measuring them This had been shown to be true for duration of life and growth. When measured in the *same* organism there was a negative correlation between rate of growth and duration of life All this evidence pointed to the conclusion that duration of life varied inversely as the rate of living—i e , the rate of expenditure of energy Prof Pearl ended with a warning that these results were not final and that mortality like other biological characteristics was essentially capable of change

Reviews and Notices of Books.

CYSTOSCOPY

By JAS B MACALPINE F R C S, Hon Surgeon and Surgeon in Charge of the Genito-Urinary Department Salford Royal Hospital Bristol J Wright and Sons, Ltd 1927 Pp. 284 25s

WITHIN less than 300 pages Mr MacAlpine has written an account of cystoscopy, as practised in this country, which contains all the information essential for the performance of this rather specialised method of examination The author deserves special praise for his straightforward simple instructions, by following these the beginner will avoid many pitfalls and overcome the many difficulties which will beset him in his earlier experiences Surgeons and patients alike will profit by the author's frank declaration (p 37) that the local application of novocaine to the urethral mucosa is often ineffective for abolishing the pain of cystoscopy in the male After the earlier chapters dealing with the construction of the cystoscope, its care, sterilisation, and introduction, are sections describing the various normal and pathological appearances of the bladder These are beautifully and faithfully illustrated in colours In the chapter on vesical tumours, full details of the method of treatment by diathermy are given, its indications and its limitations being well set out The vexed question of the treatment of ureteral stones is considered in a simple, practical way, whilst the accounts of pyelographic technique and renal function tests conform with the generally accepted teaching

Altogether the author is to be congratulated on the production of a book which is likely to rank as a standard English text-book on the subject

SURGICAL DIAGNOSIS

Exploration Clinique et Diagnostic Chirurgical Second edition By FELIX LEJARS, Professeur de Clinique Chirurgicale a la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Saint-Antoine Paris Masson et Cie 1927 Pp 911 Fr 120

THIS is a new enlarged edition of Prof Lejars's work, which first appeared four years ago It has been widely read and has achieved well-deserved popularity Its value lies in the fact that it describes in detail the ordinary simple clinical examination of surgical patients, such as is done in the out-patient department without the aid of laboratory tests The observations recorded were all made by the author, so that the reader feels that there is a substantial basis for all his statements It is an attractive book, whose reputation will be enhanced by the revision it has undergone and the addition of 187 new pictures

SEXUAL KNOWLEDGE AND HYGIENE

Sex Hygiene By Dr JULIA VON SNEIBERN and Dr ALMA SUNQUIST Translated from the Swedish by MARY E COLLETT, of Cleveland, Ohio London George Allen and Unwin 1927 Pp 114 7s 6d

Sexual Knowledge By WINFIELD SCOTT HALL, Ph D , M D Leipzig, Professor of Physiology, Northwestern University Medical School, Chicago. London T Werner Laurie Ltd 1927 Pp 320. 6s

THE book by Dr von Sneibern and Dr Sunquist, now translated into English, was originally written as a reference book for parents and teachers 15 years ago In Sweden at this time there was no mention of reproduction in the secondary school courses on biology or hygiene, and few physicians were equipped to teach on the subject It has since been kept up to date The aim in translating the book into English was to provide, in small compass, an objective treatment of the subject for teachers and college students of hygiene in America After two chapters dealing with the anatomy and physiology of the reproduction organs come chapters devoted to embryology pregnancy and delivery Next are described the hormones of the sex glands the venereal diseases the sexual abnormalities, race hygiene, and sex education The book, which contains 28 illustrations, is clearly written and well translated from the 1925 Swedish edition It is noteworthy among numerous books devoted to this and kindred topics by its complete freedom from sentiment The assumption is made throughout that the reader wants facts, and with these he is presented with the minimum of embroidery The nearest that the book gets to propaganda is to state that if it is desired that prostitution should disappear it is necessary that the attitude of men towards it be altered and that the reproduction should be prevented of persons of bad stock of those suffering from contagious diseases transmissible to the embryo, and of debilitated women But these are not so much propagandist statements as observations of self-evident truth The book well fulfils the purpose for which it was written, and can be recommended to those who, upon the subject of sex, desire more information

Dr Scott Hall's book is written in a style in which sentimentality and vehement exhortation are intimately commingled For example, to the child, desirous of knowing whence his baby sister has come, the following answer is suggested "Baby sister came out of mama's body, she was formed within mama's body out of materials drawn from mama's blood, and that is why mama's cheeks are so pale and mama's hands so thin and white", while the author describes the nefarious consequences of masturbation in terms that might cause despair to those boys who have difficulty in overcoming the habit In the medical world there is some division of opinion as to whether the habit of masturbation in adolescence is better overcome by magnifying the evils (and therefore the importance) of the practice than by treating it as a weakness of no great moment but, on the whole, better avoided The author obviously belongs to the first school, most of the modern teaching leads to the second. The virtues towards which the sexes should aspire are extolled in language, the vigour of which will probably appeal less to English than to American readers, and indeed this may be said of the whole book

MAGNETISM AND MAGIC.

By BARON DU POTET DE SENNEVOY Edited and translated by A H E LEE London George Allen and Unwin 1927 Pp 154 6s

Baron du Potet (1776–1881) was an idle child who took to mesmerism in early manhood and practised the magic art with great success through a long life About 1838 he visited England, and in cooperation with his fellow in the faith, Dr John Elliotson, treated patients at University College Hospital until the Managing Committee interfered In 1852 he wrote "La Magie dévoilée," of which this is an abbreviated translation It represents an entirely uncritical and unintelligent attitude towards the subject, and Mr. Lee would have been better advised to have issued his own interesting historical introduction and biography of Du Potet and left the Baron's own writings in the obscurity which they deserve All open-minded persons must allow that it is conceivably possible that one mind should influence another without the customary means of communication and that the mind should on occasion have an exceptional influence on the body But whether the possibility has received adequate demonstration is a question which needs far more serious discussion than Du Potet could give it

NORMAL HISTOLOGY

Thirteenth edition By G A. PIERSOL Revised and reset by WILLIAM H F ADDISON, B A, M D, Professor of Normal Histology and Embryology in the University of Pennsylvania London J B Lippincott Company 1927. Pp 477 25s

THIS book, in its revised form, has been designed to serve as a basis for the study of pathological histology Since the author has described only human tissues the matter is not swollen with observations on comparative histology which, however interesting to the biologist, are sometimes tedious and obstructive to the student who wishes to refresh his memory on a point of human structure Special attention has been given to those organs whose histology must be studied before disease processes as revealed at autopsy can be understood, and less space is given to descriptions of such tissues as yellow fibrocartilage In the system of classification, areolar tissue has been deposed from the position of eminence which it has held in many English text-books—namely, as a principal form of connective tissue—and figures merely as a synonym for loose fibrous tissue; teachers of normal histology in this country would do well to follow this lead It is disappointing that the author has dismissed the reticulo-endothelial system so briefly A summary of the histology of this system would be useful to the medical student, not only as an introduction to a subject of which he will hear much in his pathology course, but also as a study which gives a comprehensive view of the nature and function of tissue cells

The book is profusely and excellently illustrated The 432 illustrations, 43 of which are in colour, are well chosen and so arranged that their relations to the printed matter are readily seen In an appendix of 29 pages a helpful guide to histological methods and technique is given This includes a very short account of tissue cultivation, micro dissection, and supravital staining of blood The author cites the Parlodion method of embedding tissues as that most usually selected for "the production of thoroughly good preparations for general histological study." Many histologists will not agree with this dictum The terminology used, for example, basophilic granulocytes, epiphysis cerebri, &c, is not a familiar one in this country and may puzzle the British medical student These points are, however, far outweighed by the fact that the book is concise and the teaching sound

BOTANY

Plant Autographs and their Revelations. By Sir J C BOSE, F R S London · Longmans, Green and Co 1927. Pp. 231, 120 text figures. 7s 6d

FOR a quarter of a century the author has been analysing the activities of plants, and especially their movements, by adaptations of the graphic methods familiar in physiology which he has in some cases refined to about the limit of their accuracy His researches have been made known in a number of publications, and he here gives a semi-popular account in which he covers the whole field This summary is uncritical in the sense that he takes no notice of objections to his methods and results which have been raised by other plant physiologists, and the general reader would have appreciated some statement of the difficulties in the way of accepting the author's view that plants have a nervous system closely analogous to that of the higher animals The frontispiece is a good portrait of the author, and the volume appropriately closes with a picture of the Institute in Calcutta which commemorates his devotion to the pursuit of knowledge

READABLE SCHOOL BIOLOGY.

By O H LATTER, M A, late Science Master at Charterhouse London: G Bell and Sons 1927. Pp 143, 48 text figures 2s 6d

MR Latter has for so long been known as one of the relatively few successful teachers of biology in our schools that this summary of his mature experience will be examined with attention and respect The book hardly covers what is generally known as "biology"; it deals rather with the individual physiology of animals and plants without much reference to their relations to the rest of the world As we should expect from such a teacher, there is no attempt to pretend that there is any easy road to knowledge, the subject matter is solid and the treatment serious We note, too, the emphatic opinion that practical work is waste of time for pupils who are taking biology as part of a general education But why the book should be called "readable" is not obvious It seems, in fact, to be a highly condensed summary which will surely need a good deal of elaboration and explanation in class Technically it may be noted that there is a good deal of doubt whether the "gills" of mussels (p 28) are really or mainly respiratory in function

BOOKS TO READ.

To begin with, being Prophylaxis against Pedantry. By RAYMOND PEARL London and New York A A Knopf 1927. Pp 96. 6s.

Prof Pearl has made a list of 70 books which he thinks would form a good basis for the reading of his graduate students who purpose to become biologists, biometricians, and vital statisticians It is a varied catalogue—Lucretius, Lucian, Rabelais, Mencken, Hugh Miller, Darwin, Yule, and most other sorts—and without doubt anyone who worked earnestly through the list would be very much the better for it And if anyone does, Prof. Pearl will laugh, and say that that shows they have missed the main point of his introductory chapter and running commentary. A wealth of learning sits lightly on the author, and he is always welcome as one who can be serious without being solemn But he is not quite at his best when he lets his humour have its way; it slips rather easily from comedy to farce All of us will find that we have not read several books which are necessary for our educational salvation; the practical bibliographical notes will help us to get ourselves straight

THE LANCET.

LONDON, SATURDAY, JUNE 25, 1927

THE PERSISTENCE OF THE SLUM

A NOTE of complacency has recently crept into icial statements regarding the housing programme, contrast with the situation revealed in the ports of medical officers of health which we mmarise from week to week A short time o Sir **KINGSLEY WOOD** said that since the mistice 866,000 new houses had been completed, fewer than 217,000 of these within the twelvemonth ded on March 31st last , and in an admirably lucid apter of his recent book [1] dealing with the shortage houses due to the cessation of building during the ar, Lieut -Colonel F E **FREMANTLE**—putting the mual need of houses at 120,000 and the present annual itput at 190,000—calculates it should only take till id-1930 to reach conditions better than those isting in the pre-war census year of 1911 But all is building has only touched in the smallest degree, at all, the conditions under which the really poor e housed The Minister's total of 866,000 houses cludes 112,742 that are rated above £26 per num Even when the grosser forms of post-war ercrowding have ceased to exist there will still main, as Mr **NEVILLE CHAMBERLAIN** writes in prefatory note to Colonel **FREMANTLE**'s book, e problem of the slums It is hardly possible, r is it strictly necessary, to define exactly what is eant by a slum The fact that it is cognate both with e word slump and the German word for mud fficiently indicates the dual aspect of the problem uch it creates For while, as Mr G H **DUCKWORTH** ites in a Special Slum Number of *Garden Cities and wn Planning,*[2] the slum inhabitants are not cessarily *very* poor or necessarily bad, they are ually thriftless, irregularly employed, rough in their inners, and unclean, thus constituting a social orld of their own On the physical side disease urishes in slum surroundings Sir **JOHN ROBERTSON** mpares two artisan areas in Birmingham of approximately the same size, in one of which the houses are id, and in the other fairly good The former has a rth-rate of 33 and a death-rate of 21, compared with and 12 in the latter The infant mortality among e badly housed population is almost double, the ath-rate from measles more than treble, from irrhœa quadruple, that of the better-housed district king typical slum areas in three county boroughs **FREMANTLE** finds the death-rate from tubercle each case to be more than twice that of the rate in e whole city But the slums are not saddled with ysical disease only, for, as he says, it is in them that e dregs of mankind converge in the most decadent uses and the least delectable districts, men and uses together constituting the slum , the casualties modern life are sucked down into it by the thousand d fasten on it a reputation from which both men d houses suffer until recovery becomes beyond pair. That, at all events, is not too lurid a picture the situation in London

In the same issue of *Garden Cities and Town Planning,* the Editor, Mr W L **HARE**, puts together figures drawn from official sources during the five-year period 1920–24, giving a more exact picture than can be found elsewhere of the present state of insanitary housing During this period 7½ million houses were inspected by local authorities under various Acts and regulations, when 1½ million of them were found to be either unfit or not reasonably fit for human habitation The number is ominously large, although the standard set by sanitary inspectors is believed not to be unduly exacting Something like 1¼ million houses were rendered fit in obedience to the authorities, leaving 174,426 whose condition was more serious Of these, 12,690 were ordered to be closed, but 3023 were reopened on being rendered fit, the "fitness" being presumably a temporary quality Of the condemned houses only 3111 in the five years under review were actually closed, and on the positive side 3898 dwellings in all were supplied in place of demolished slums, making a miserable credit balance of only 787 houses At this rate of progress elimination of the unhealthy area will not be a question of years but of generations Nor is the abolition of the slum easily amenable to the solution of providing alternative dwellings The cry of the slum-dweller is ever to be rehoused in cottages on the same site, for by removing a man from his work hours are wasted each day in travelling Cottages, however, cannot be built in cities and these people have an instinctive dislike to the block buildings which would make it possible to provide them with adequate homes near their work, preferring to have a bit of yard and space to keep poultry or rabbits Scottish experience, furthermore, shows that in tenement dwellings children are kept indoors at the expense of their health and spirits, and it is certainly a sound principle that in all rehousing schemes the main object should be ease of access to the open air in the interests of the children rather than proximity to work in the interests of the breadwinner A practical difficulty, however, lies in the fact that in London and the big cities the passenger traffic at the rush hours is already approaching its limits, and no doubt the final solution will be found in the "grand policy" of the Garden Cities Association, which consists in the removal of a certain body of industries, along with the population serving them, to satellite towns on rural sites

The problem is not as hopeless as is supposed by those who hold that the slum-dweller carries the slum to whatever surroundings he is moved Experience in Glasgow has convinced Dr A S M **MACGREGOR** that rehousing does eliminate the greater part of their "slum qualities" Out of 835 removals the results were reported as very good in 510, and only 44 were "dirty" after the change Unhappily, even in their present state, the slums are often lucrative property, and to buy them up at market value would be almost prohibitive in cost, though it is to be noted that under the 1925 Act the basis of compensation, where buildings are closed on account of their insanitary condition, is the value of the land regarded as a cleared site Moreover, it is untrue to say, as many people do, that nothing can be done to improve conditions until money is found for the reconstruction and removal of dwellings The problem is not one of building alone Even assuming, as Mr **CHAMBERLAIN** does, that a very large proportion of workers must continue to live near their work in present-day industrial centres, there is much to be hoped from enlightened management of house property Mr **CHAMBERLAIN** has given his deliberate opinion that the faulty management of the past has been largely responsible for the carelessness and destructiveness of the slum tenant It was, as everyone knows, the late Miss **Octavia Hill** who showed how the business of rent collecting undertaken by women of tact and sympathy without a hint of meddling or intrusion, might become a great humanising force Even now many local authorities are able to secure all necessary repairs by friendly conference with owners and without recourse to statutory notice An Association of Women's House Property Managers[3] is carrying on the work begun by Miss **Hill**, and public utility societies are beginning to acquire and renovate house property in congested districts There is here a great opening for the service of trained women

BASAL BRAIN TUMOURS

The few surgeons who have as yet specialised in surgery of the base of the brain have not been discouraged by the extreme difficulties associated with the removal of basal tumours from their inaccessible situations, knowledge has gradually been accumulated by them, with the result that the removal of part of the pituitary body or a tumour of the acoustic nerve are recognised procedures Clinically, basal brain tumours often grow in the neighbourhood of large and important nerves, so that they can be accurately localised, although they are quite difficult to reach Thus acoustic tumours give very distinctive signs, and there appears to be another group of tumours which grow from the front part of the cranial cavity in the olfactory grooves, exerting pressure upon the olfactory nerves and the frontal lobes, and ultimately giving rise to symptoms suggesting pituitary new growth Successful excision even of a tumour lying in the olfactory groove can now be contemplated

Our present issue contains good evidence of the interest shown in this difficult branch of surgery by leaders of surgical thought outside this country Prof **Harvey Cushing**, of Harvard, has taken the meningiomas which arise from the olfactory groove as the subject of his Macewen Memorial Lecture Dr **Oskar Hirsch**, of Vienna, calls attention to certain clinical phenomena of pituitary tumours, describing especially the ocular symptoms associated with them Speaking with the authority of one who has performed 100 operations upon hypophyseal tumours, he divides tumours of the hypophysis into two great groups a benign group in which simple adenoma is present, and a malignant group comprising tumours which, whatever their minute structure may be, take on a malignant character The fundamental difference between the groups lies in their mode of growth in the former the tumour does not tend to emerge from the pituitary fossa upwards into the general cavity of the skull, extension upwards is characteristic of the second group The optic chiasma does not lie directly in the optic groove, but somewhat above and behind it, and it is only pressed upon by a pituitary tumour which emerges from its fossa The ocular signs are primarily an optic atrophy with bitemporal hemianopia, papillœdema and active neuritis are uncommon phenomena If they exist, the diagnostician should be sceptical of the existence of a pituitary tumour unless other symptoms render it a certainty Prof **Cushing** describes the clinical features of tumours which originate in the neighbourhood of the olfactory groove They are not very common, but when they occur they give rise to a clinical picture which can be recognised provided that a careful history has been taken Having established the presence of such tumours it became necessary to devise a technique for their removal, radical extirpation in the case of a meningioma giving the patient a good prospect of permanent cure The growth is reached by an osteoplastic approach from the front, just as an acoustic tumour is reached by exposing the *cerebellum* There is another parallel between the two tumours in that their removal is accompanied by the danger of severe hæmorrhage One patient upon whom Prof **Cushing** operated survived, but only after passing through a serious illness and submitting to three operations in each of which the danger of hæmorrhage was encountered It was then that Prof **Cushing** turned his attention to methods of removal other than simple curettage The first patient upon whom he used modern electro-surgical methods, to which we recently called attention[1], passed through the ordeal without running any serious risk and with relief from his tumour at one sitting The performance was repeated on another patient with a similarly happy result The operation demands the most exacting attention to detail and the avoidance of all hæmorrhage, the first tumour took seven hours and the second one nine hours to remove The apparatus used by Prof **Cushing** is one devised by Prof W T **Bovie**, it resembles **Wyeth's** endotherm knife in that both coagulating and cutting currents are combined in one machine, but in **Bovie's** instrument the current is so powerful that for both purposes a loop may be employed in place of the straight needle. Such operations imply the utmost endurance on the part of surgeon and the theatre staff, but now that the way has been pointed out, development of technique should shorten the time required The restoration to health, by the removal of tumours from the base of the skull, of two patients who had become mentally deficient is a new land-mark in surgery.

◆

ANÆSTHETICS AND INQUESTS.

From time to time public apprehension about the danger of anæsthetics appears to be quickened to an almost unreasonable pitch The cause of this state of fear, which seems to be entirely unjustified, is no doubt mainly the publicity given to fatalities occurring during anæsthesia This publicity is often so scanty and indiscriminating, and therefore so startling, that the ordinary newspaper reader is naturally alarmed He has not knowledge enough, nor is he sufficiently supplied with facts to realise that in many cases the death which alarms him was not due primarily or even mainly to an anæsthetic It is the fashion to-day to believe in the universal benefaction of publicity, "bring the truth to light," "expose all the facts"—these and similar slogans are the general recipe for avoiding trouble in public and private affairs A departure, however, has recently been made in the law which prevents full reports of divorce proceedings, and it may be argued that there are other topics on which a discretionary silence serves the public better than does full publicity It is certainly open to question whether this doctrine does not apply to reports of fatalities during anæsthesia The advocates of publicity maintain that it is by public inquiry alone that the minds of relatives and friends can be adequately set at rest and that they can be assured that there has been no question of negligence or lack of care Surely a private inquiry conducted with the same consideration and thoroughness that the coroner now devotes to his task, but not open to public description, would be equally convincing to all concerned? The present publicity of these inquiries may, indeed, have the advantage of deterring the inexperienced from running the risk of having to appear before the coroner and

---

[1] The Lancet, May 14th, 1927, p 1031

explain an anæsthetic fatality. They have, however, the undoubted disadvantage that they instil fear into the public mind, thus deterring from operation some who would benefit by the surgeon's aid, and leading others to take anæsthetics in such trepidation that the possible dangers of the process are increased to the maximum. They may have moreover, a disastrous effect on the nerve of any young administrator of anæsthetics who has been so unfortunate as to figure in the coroner's court.

That the actual number of deaths during anæsthesia has risen in recent years no one in possession of the facts will, of course, deny. Some of these facts were set out recently in our own columns by Dr. A. G. LEVY.[1] In his annual report for 1925, which has just appeared, the Registrar-General gives 442 as the total number of deaths under anæsthetics occurring in that year, a number which, he remarks, is for the sixth time in succession considerably higher than in any of the years from 1911 to 1919—1911 being the first year in which complete figures were available. That the number of deaths has increased out of proportion to the increase in the number of operations performed is, however, not the experience of the large hospitals which keep accurate records; in these institutions at any rate, the proportional death-rate of anæsthesia has not only not risen but has actually diminished. It is obviously impossible even to guess at the truth for the country at large. Who has the least idea of the number of operations performed daily in innumerable small and cottage hospitals, and in private practice? There is no available register for the anæsthetics in these thousands of cases. Yet a single fatality occurring among them most probably comes to light and attracts attention. Another fact to which attention has been prominently directed is the increase in the number of deaths due to ether. In 1925 ether was the sole anæsthetic used in 113 cases as against 83 in which chloroform alone was given. But here again it is common knowledge that ether has largely replaced all other general anæsthetics as the routine agent for the conduct of major operations. It is only to be expected, therefore, that the number of fatalities put to its discredit would rise in accordance with the great increase in serious operations. It is doubtless true that this preponderating employment of ether, particularly in very grave operations, has made more obvious dangers which are involved in its extensive use and also, as shown in a recent article by Dr. S. R. WILSON,[2] the importance of using only ether of the strictest chemical purity.

There is, then, a certain amount of dissatisfaction with the present system of inquiry into deaths from anæsthetics. This dissatisfaction exists not only on the part of anæsthetists. Coroners themselves are not all entirely satisfied with the present arrangements, for they are aware that the notification of deaths is not so complete as they would like to see it, and that in the recently amended Coroners' Bill no notice has been taken of the recommendations of the Home Office Departmental Committee, which reported as long ago as 1910. The objection which anæsthetists raise to the present procedure is twofold. First, they disapprove of the unreasonable grounds on which an inquiry is demanded and secondly, they disapprove of the nature of that inquiry. Regarding the second objection, they maintain that the anæsthetist is often exposed to an interrogatory which suggests that he has been guilty of a misdemeanour, and that his conduct is being criticised by a man who possesses no special knowledge to justify him in adopting the critic's rôle. Further, the anæsthetist contends that these inquiries not only do nothing to further scientific knowledge and so help to diminish danger, but also waste valuable information which might be elicited if they were otherwise conducted. As regards the reasons for holding the inquiry at all, the anæsthetists maintain that it is illogical to separate those deaths which are apparently due to anæsthetics from those that are apparently due to operation, holding the former as not natural, and the latter as natural deaths. In a great number of these cases, of course, it is a nice question how far the anæsthetic, and how far previous illness, operative shock or hæmorrhage has been the cause of death. It is obvious that no finality has yet been reached either in reducing anæsthetic deaths to their lowest possible figure or in investigating them, when they do occur, in the most advantageous way.

Annotations.

"Ne quid nimis."

THE ECLIPSE AND DARK-ADAPTATION

WE have already dwelt on the danger which awaits those who view the coming eclipse of the sun with the naked eye, and pointed out the precautions which it is necessary to adopt. The warning applies not only to those who may be fortunate enough to witness it in the zone of totality, but to those who, supposing next Wednesday morning to be cloudless, may be interested enough to watch the partial eclipse, visible from any part of the country. For those in the zone of totality, dark or smoked glasses, or a specially prepared film, are only necessary before and after the sun's disc is wholly obscured. During this short phase the observer is better without it, and in order to see the unique phenomena to the best advantage it is essential that the eyes of the observer should be kept in the dark beforehand, preferably for some 20 minutes—that is to say, they should be "dark-adapted." If anyone goes from a well-lit room into a completely dark one it is only gradually that he can see anything at all. In the same way, those observers in the zone of totality who do not take care that their eyes are dark-adapted will miss some of the features which should be visible during the 20 precious seconds to those who have taken it. Without this precaution, indeed, Dr. Waterfield tells us, the corona, except for its bright lowest layers, will be very difficult to see.[1] He suggests a simple way of securing dark-adaptation by means of an opaque mask, lined say with velvet, in which are two eyeholes occupied by screens so deeply tinted as to allow the sun to be only just visible—the mask to be removed the moment the totality phase begins and replaced the moment it ends. Such a mask, with removable screen, either of a uniform darkness or of a graduated tint which can be easily placed in the position in which the appropriate shade is obtained, has been put on the market for the special purpose of this eclipse.[2] Those who see it without such a device must take special care to replace their dark glasses (or other shading apparatus) the moment the sun's crescent reappears out of the shadow.

HOUSE DUST AND ASTHMA

THE part attributed to inhaled proteins in the production of the typical symptoms of hay-fever and asthma adds yet another to the long list of immediate exciting causes of these diseases, though we should hesitate to ascribe to them all ætiological significance. Dr. A. H. Rowe[3] has recently published a study of 162 asthmatics and 20 patients suffering from hay-fever in whom he carried out an investigation with various kinds of house dust. The work was done in California, where pollen of one kind or another is present in the air for ten months in the year. In his series of cases Dr. Rowe found 42 per cent. of patients sensitive to house dust extracts and he believes that certain patients who develop asthmatic attacks a few hours after retiring to bed may be sensitive not only to those substances which go to the make-up of their bed-clothes, but also to the dust of the bedroom which gradually accumulates on the mucous membranes until enough absorption has taken place to cause symptoms. He notes, further, that these dust-sensitive patients are often worse in the winter months when they tend to be confined to their rooms for longer periods of the day. It has been suggested that a new specific principle in house dust may be responsible for sensitisation in these cases, but Dr. Rowe, after testing a large number of such dusts, is not in agreement and considers that various vegetable and animal particles are responsible in different cases. The data collected by him, indeed, show that reactions to dust rarely occur without one or more positive reactions to proteins commonly used in sensitisation testing. In all such cases desensitisation should obviously include very thorough cleansing of living and bedrooms.

[3] Rowe, Albert H.: Archives of Internal Medicine, 1927, xxxix., 498.

On somewhat similar lines is the work, an account of which appeared in our columns last week, of Prof. W. Storm van Leeuwen, Dr. W. Einthoven, and Dr. W. Kremer on climatic allergens. These authors recognise two groups of asthma-inducing substances in air: group A found in the open air and group B in private houses where presumably dust is allowed to accumulate. The nature of the allergens of group A is unknown, though the authors consider they have proof of their existence; whilst group B probably includes many substances, amongst which Prof. van Leeuwen considers the fungus *Aspergillus fumigatus* to be an important one. This fungus is especially liable to grow in damp, ill-ventilated houses. The authors have devised several methods of removing these climatic allergens: one of the important means being a special air-tight sleeping chamber suitably ventilated by mechanical means. Two years ago a clinic was started in Leiden, and the authors record good results not only with asthma but with whooping-cough and pulmonary tuberculosis. Quite apart from the difficulty of interpretation in the case of the last two diseases, the asthma group is, of course, notoriously complex and many ætiological factors may be at work. The researches cited above seem to suggest that the inhalation of protein matter, especially of fungi, may be the immediate exciting cause of one group of cases. In this case modern methods in house construction and decoration, with the abolition of all heavy curtains and carpets, seem likely to have an important bearing on cure.

FOOT-AND-MOUTH DISEASE.

DURING the past two years British, German, American, and Scandinavian workers have shown great activity in the investigation of foot-and-mouth disease. A further instalment of detailed research carried out by Dr. S. P. Bedson, Mrs. Y. M. Burbury, and Dr. H. B. Maitland for the Foot-and-Mouth Disease Research Committee of the Ministry of Agriculture has been published in the *Journal of Comparative Pathology and Therapeutics* for March, 1927. The period covered is the same as that of the Second Progress Report noticed in THE LANCET of March 5th (p. 499), but certain aspects of the subject are considered in greater detail. The paper is in three parts, the first of which deals with the possibility of producing an active immunity apart from an attack of the disease. Not long ago this was generally held to be a hopeless pursuit, for until last year it was agreed that a dead vaccine gave no protection, and many observers doubted the existence of any notable immunity even after an attack of disease. The first of these bogies ceased to hinder progress when Vallee, Carré, and the British workers whose names are given above showed that virus treated with formalin and used as a vaccine produced a very definite immunity. In guinea-pigs the resistance is of a fairly high grade, comparable to that following a dose of immune serum, and in these animals it appears with surprising rapidity and lasts for some weeks. The observation that repeated attacks might affect the same animal within one year had a disheartening effect in the past, but these early recurrences of the disease have been explained, and to some extent discounted, by the discovery that there are two or more distinct immunological types of foot-and-mouth disease which do not protect against one another. The existence of these immunological types is now recognised in France, England, Germany, and Sweden. The subject of prophylactic vaccination is still only in an initial stage of experiment, and it is much too early to assess the possible value of a vaccine, especially as very few experiments with cattle have so far been made and polyvalent vaccine would be required. One great obstacle to the practical use of such a method is the difficulty in obtaining large quantities of virus from which to make vaccine, since propagation of the virus in artificial culture has not yet been achieved. The second part gives an account of experiments dealing with the survival, sometimes for several weeks, of virus dried in the air on different materials. This important work is far from finished and the conditions which promote viability need much further study. The third part gives the results of attempts to infect rabbits and rats. They do not suggest the existence of a natural disease in these animals, but are interesting because they show the difference of susceptibility in allied species or races—e.g., in wild and tame rats. The American Commission which has been working at Strasbourg during 1926 has recorded some interesting observations on the similarity of vesicular stomatitis of horses and foot-and-mouth disease of cattle. P. K. Olitsky and L. Boez,[1] two members of this Commission, have especially studied the resistance of the virus to alcohol, recorded by the English observers, and put forward the view that the virus is protected by the coagulation of particles of serum protein around it, even when the amount of serum present is very small. They show that if alcohol is used in a liquid with a pH of 8.2 the virus is killed as quickly as staphylococci, and they attribute this to the absence of coagulation of the proteins under these conditions. H. Magnusson and K. A. Hermansson[2] in Sweden have confirmed the existence of two types of disease in their country, have made observations on the occasional rapid disappearance of infection from cattle stalls, and have searched for but failed to find evidence of human cases or carriers of the disease which C. Kling considered a probable source of danger. Altogether the rapid strides made of late in the study of this scourge of agriculture, and the continued activity of research workers in different countries, are of good presage for the future. It is encouraging to find so many facts now known about the disease and its virus where two or three years ago there was little save conjecture.

THE CASSEL HOSPITAL

THE fifth annual report of the medical director of the Cassel Hospital at Swaylands is issued in a new form. The tables published in previous years have been omitted, and the report consists of a review of the patients discharged in each of the years since the hospital opened. The results have been encouraging, so much so as to emphasise still further, if it be possible, the great and increasing need of the country for more institutions of this kind. The psychoneuroses are becoming more common every year; they are responsible for as much misery and loss of efficiency as any other class of disease, and they are comparatively curable. Many persons go to Swaylands quite incapacitated by some failure of mental function which can be remedied by relatively simple means; they are discharged healthy and useful citizens. A far greater number of similarly afflicted persons still continue untreated, largely because they have nowhere to go, until they are certified or attempt to take their lives Along with the provision of more new accommodation, a vigorous extension of facilities for voluntary treatment is essential if the country is to meet the ever-growing demand created by the increasing complexity of civilised life During 1925 182 patients were discharged from Swaylands, 28 of them for more than the first time Of the 93 suffering from psychoneuroses who have reported on their condition after a year in the outside world, 69 state that they are much better, 23 that they are unimproved, and 1 that he recovered after an operation Of the psychotic cases, 5 out of 8 suffering from depression have recovered, but 7 schizophrenics and 3 hypochondriacs did not benefit One of the most valuable features of the Cassel system is the care with which patients are observed after their discharge and the reports received from patients discharged in the years previous to 1925 form a gratifyingly large percentage of the possible number The medical director makes an interesting comment on the fraction of patients who report that they were unimproved when they left but got better soon afterwards. The one outstanding basis of classification in functional nervous disorder is, he says the response to the question "Is the patient willing to take up the responsibilities which cure implies, or is he unable to face them?" If he is willing, his recovery will be comparatively easy, if he is unwilling it will be difficult The willing patient is a puzzled person who has lost his way, and any reasonable plan will help him To benefit an unwilling patient may however, be a most complicated task. It may involve changing not only his environment but certain aspects of his character. Now, most of the patients who said they got well after discharge but not before, were those between whom and the doctor there had been a considerable amount of friction or dislike It is a commonplace that a patient enters on analytical treatment with a considerable amount of unconscious resistance and that when this is resolved his relations with his physician become proportionately improved The patients Dr T A Ross describes here are, however, generally those whose "negative transferences" persisted up to the date of their discharge It is quite natural he says, that they should not have been able to accept help from someone they had considered unsympathetic It is not unreasonable to infer that most of them had benefited from the Swaylands treatment more than they were willing to admit, even to themselves One, for instance, was immediately cured by another course of psychotherapy, another by a few enemata of plain water, a third by faradism Dr Ross's report is outstandingly different from the ordinary mental hospital report good though that often is It contains clinical matter of great value and all who devote themselves to the psychological and functional aspect of psychiatry will find in it much to interest them

[2] Acta Path. et Microbiol. Scand., 1926, iii., 737.

THE LONGER CATECHISM

THE immense importance of obtaining a correct clinical history is universally acknowledged, it is one of the criteria by which the efficient medical man is distinguished from the inefficient, the conscientious from the careless Our sympathy therefore is readily attracted by any suggestion which may seem to make casetaking easier and more effective Under the title of "Automorbografia" Dr Emilio Mira Director of the Institute of Professional Orientation in Barcelona propounds a plan which aims at bringing this about[1] His suggestion is that every patient should be provided with a questionnaire somewhat in the form with which we are all familiar in the case of insurance companies but vastly more elaborate, to be filled up before coming to the doctor The schedule is a formidable one occupying two and a half quarto pages, and containing over a hundred questions which cover every detail of the patient's daily life, his tastes habits and occupations, not to mention his mental and moral equipment It is preceded by a few lines of instruction and explanation of the reasons for this request, and an assurance that it is quite confidential

It may be said at once that this is one of those admirable projects often miscalled counsels of perfection, which everyone applauds and hardly anyone ever adopts for the simple reason that in a busy world life is not long enough. At a moderate computation it would take two hours to fill up the form conscientiously and in a large proportion of cases many of the questions could only be answered doubtfully or not at all Patients are asked to say, for instance on what milk they were reared to describe hour by hour and "with all minuteness" a day and night of their ordinary lives, and to estimate their own characters In England at all events it is certain that many patients confronted with such an inquisition would seek another physician; the neurotic alone would welcome it as an excuse for giving a life-history of his woes And yet there is much to be said for a short scheme which would enable the patient to see with what questions he will be faced and to fill in dates and facts of family or personal history which would require time to recall But oral examination cannot be dispensed with, it gives an insight into the character and credibility of the patient which nothing else can and notwithstanding the author's instances to the contrary often brings out facts which would not be put down in writing To answer an interrogatory with real accuracy requires more training and practice than the average patient, even of the better class possesses hence, either much time must be spent on cross-examination or many inaccuracies will remain in the dossier

The value of such dossiers assuming that they are carefully and conscientiously filled up, for statistical purposes cannot be denied—Galton demonstrated that in a somewhat different sphere—but in daily work they introduce an amount of superfluous material which hinders practical decision, despite the advantages ably set forth by the author The fact that the author has made more or less successful trial of different models of the questionnaire in 752 cases suggests that this method may suit the Spanish habit of mind

INJECTION TREATMENT OF VARICOSE VEINS

LAST year we commented[1] on Dr. V. Meisen's method of treating varicose veins by injecting a 20–30 per cent sclerosing solution of sodium salicylate Dr Meisen has now published an account of the extension of his experiments[2] His results have continued uniformly good, and he has evolved a modification of technique by which he has succeeded in avoiding severe complications in all but 1 6 per cent. of his patients even in the presence of ulcers and eczema He lays stress on the importance of a most painstaking examination. He objects to the use of the elastic band which he says leads to stasis, and makes the patient stand on a high chair and lift each leg alternately while he observes the state of the veins under working conditions. It is important to look carefully for varices hidden under fat ulcers and other skin lesions He has replaced his original solution by one composed of equal parts 25 per cent sodium salicylate and 10 per cent common salt, which is practically painless when injected The maximum dose is 10 c cm. The point of the cannula must not be too sharp or the vein may be transfixed It is inserted while the patient is standing up, and when blood flows from it it is rotated once or twice to make sure that it has not caught in the opposite wall The patient then lies down, and the surgeon places the leg on a special stand. When the varices are empty, which takes a few minutes the injection is commenced, this should be performed very slowly and stopped if there is any resistance to the flow or if the patient feels pain For injections in the neighbourhood of the malleoli, which are always painful, ½ per cent novocaine (without adrenalin) is given direct into the varix After injection the part is lightly massaged Treatment is repeated every other day, and if both legs are affected one is done every day.

[1] THE LANCET 1926 ii 661

[2] Ugeskrift for Laegar, Jan. 20th, 1927

The patients Dr Meisen has treated include 55 with phlebitis, 135 with varicose ulcers of varying duration, and one with venous angioma Forty patients had chronic eczema as a complication Old age offers no counterindication, and the oldest patient treated was 81 All the ulcers were healed at the time of discharge except in two cases, some, however, required a further short course In his previous *communication Dr Meisen already noted the curious* fact that 25 per cent. of his patients had flat feet, he now raises his estimate of the coincidence of flat-foot and varix to 50 per cent Another complication is periostitis of the tibia, which often proves very stubborn Only 3 per cent of his cases had undergone previous operation, and most of these had had recurrences after the Trendelenburg technique, several had had repeated surgical treatment The author's opinion is that operation is useless for this complaint. He has observed that varices appear at very definite points—viz, on the anastomoses between the deep and superficial veins If, as has been believed, they were simply due to weakness of the vessel walls, they would appear haphazard, which actually they do not. This is one reason for the disappointing results of operation, for it is impossible to remove these anastomoses The operation cannot be radical enough The 1 3 per cent of complicated cases included deep sloughs leading to gangrene of muscle, chemical phlebitis, infarction, and hæmorrhage Infarcts are sometimes the result of using too large doses, and occurred in one or two cases for whom an attempt was made to hasten the treatment at their request 25 c cm is regarded as an infarct-producing dose, and 10 c cm is now Dr Meisen's maximum He also hopes to forestall this accident by ligating the vein when this appears advisable The number of bad results has, however, been unusually small for an experimental treatment That the method produces a very firm thrombus is proved by the failure of heavy massage at a Turkish bath to displace it on the day after injection

Dr. Louis Humbert, in a treatise on the same subject,[3] quotes the work of several authorities who have relied on different sclerosing solutions Sicard, whose paper published in 1919 was the pioneer work on this treatment, began by using neutral sodium carbonate, having observed the rapid venous sclerosis caused by salvarsan compounds with their high sodium content This substance, however, proved highly irritating to the subcutaneous cellular tissue and was often responsible for scarring, even when the operation was perfectly performed He now, like *Dr Meisen, prefers sodium salicylate to everything* else, but also uses mercury biniodide, especially for varicose ulcer This compound was first employed by Montpellier and Lacroix but it has the disadvantage of being toxic, and cannot be freely injected into several places at once Génévrier uses a solution of 0 4 g of neutral quinine hydrochlorate and 2 g of urethane in 3 c cm of water, but Dr Humbert considers that quinine should not be given without great care It has been known to cause extensive fibrosis. Sodium citrate he considers inferior to the salicylate, and mercury bichloride, he states, has caused several accidents He recommends a technique very similar to that of Dr Meisen, and describes some leg supports which he has designed and which increase the ease of operation and the comfort of the patient The most brilliant successes, he says, are obtained in cases of obvious varices where there is no lesion of the skin He claims that 98 per cent of ulcers are curable by this method, and that it is the only one with any reasonable chance of success in varicose eczema Injections, however, are counterindicated in the acute stage of deep phlebitis. The classic treatment should be followed by some months of elastic bandaging, and the sclerosing process instituted when the veins are normal The veins will always be hypersensitive, however, and phlebitis can be diagnosed retrospectively by the acute inflammatory reaction, followed by œdema, which is apt to take place when a vein once phlebitic is injected Patients are liable to relapse after an infectious illness, and injury, or any physical adversity, however slight For this class of sufferers small doses and weak concentrations are used at long intervals, the smaller and more sensitive veins are irrigated *gently, and the large trunks left to the last* Adhesive bands are used freely and, in fact, Dr Humbert, stresses their use in all cases more emphatically than Dr Meisen Besides its efficacy, the injection treatment of varicose conditions has the great advantage of allowing the patient to proceed almost unhampered with his work Probably the large majority of varicosities are due to much standing in the pursuit of some humble avocation, and the patient is unable to afford either the cost of an excision or the time during which it will incapacitate him from work The sclerosing operation will prove a great boon to this numerous class if these successes can be substantiated

SHELL-SHOCK AND ITS AFTERMATH.

WITH the passage of almost eight years since the end of the Great War the problem of the shell-shocked soldier still remains with the United States as it does with us The question of the war neuroses has proved to be not merely a medical one, but a social one also Why do the shell-shock cases still remain? Is the war neurosis a specific nervous disorder arising out of very definite conditions? What can society do with those whose power of adaptation seems to have been destroyed beyond repair? These are some of the questions upon which Dr Norman Fenton attempts to throw light in a book recently published[1] The subject *lends itself to statistical inquiry, at least* from the medico-sociological point of view, and it is this method of approach that the author pursues throughout this interesting essay The early chapters concern the military history of Base Hospital 117, which was organised to meet the very special requirements of the shell-shock patients Coming late into the conflict America was able to profit by the experience of other nations, and in consequence the training of large numbers of psychopathologists for work in France and elsewhere was a feature of American medical organisation With this valuable instrument they were to some extent able to screen the army at the recruiting stage of those with psychopathic tendencies, and others who because of feeble mentality may have proved *themselves a nuisance to others*—their colleagues and superiors in the field of military operations

Dr Fenton deals statistically with the relationship between general casualties and shell-shock, and between shell-shock and other disorders incidental to the crowding together in a strange environment of healthy and inexperienced young men—i e, venereal disease, alcoholism, and drug addiction Age, race, geographical origin within the States, and educational standard are all here correlated with the disorder of shell-shock Race investigation, strangely enough, produced very poor data As regards age, a high incidence of war neurosis was found amongst those of middle age There was discovered a demonstrable relationship between the amount of education and the soldier's capacity to withstand the shocks of war, and it was found in the examination of post-war figures that the educated patients tended to drop out and become socially useful, whereas those of limited education or with demonstrably psychopathic taint remained on as clinically sick. The follow-up of the cases was the main aim of the author's study. In this follow-up of a group of psycho-neurotics Dr. Fenton found that the "1924–25 group is of much more use to society now than they were to the army at the time of discharge from hospital." This finding needs more careful statistical analysis. Adaptation to military life was more difficult to the neurotic than adaptation to civilian life. Moreover, education statistics merely indicate a higher social level of achievement and easier power of return to a more receptive environment. The decently educated soldier probably came from an environment much more willing to reabsorb him on his return than would be the case of the poorly educated and his less sympathetic environment. Again, in America the post-war prosperity made it easier for the war-scarred young American to find a place in the community than did conditions in England for our men. Many, it is true, were medically unfit for work, but the criterion of fitness was profoundly influenced by the economic depression and by the movements of population to the big towns during the Great War. In fact, the problem of shell-shock at this stage needs exploration of two fields. First, what are the individual characteristics which make for war neurosis? Secondly, what are the social and economic factors which are at work perpetuating such a condition? Whether the readaptation frequently achieved has been due to the actual healing of psychic scars, or whether society has been able to shut its eyes to them and reabsorb these men, can only be decided by a more careful consideration of the victim as an individual mind and as an economic unit. Dr. Fenton's book is of extreme interest to those who have had to deal with shell-shock cases, and he has brought forward data and methods of correlation which ought to stimulate inquiry in this country where war neurosis and its aftermath remains a problem.

PHTHISIS IN THE SLATE INDUSTRY.

THE question as to whether inhalation of slate dust is associated with a high death-rate from phthisis has often been raised, but never decided. Now, however, a report[1] has been issued from the Welsh Board of Health which bids fair to settle the matter. Slates are nearly a monopoly of North Wales where they are quarried in the counties of Merioneth and Carnarvon. The men who get the rock in the open terraced quarries are less exposed to dust than the men who split and dress the slate in sheds. When the mortality experienced by these men is considered in relation to their dust exposure, and to that of other men in the small rural district of Gwyrfai, which Dr. T. W. Wade intensively investigated, the influence of the industry is brought to light. All the slate workers, and in particular the dressers and splitters, experience greater mortality from phthisis than other males, and this mortality exhibits the statistical phenomena characteristic of phthisis of silicotic origin, which are that it occurs later in life than usual and is associated with high mortalities from other respiratory diseases. The excessive death-rates are far below what are experienced by some other industries with a silica dust risk, such as tin-miners in Cornwall, and metal grinders in Sheffield, but the exposure to dust in the slate industry appears to be less, as is also the content of silica in the dust. Interesting mineralogical reports are given of the composition of the slate dust; they indicate that some 35 per cent. consists of silica in the form of quartz and that particles from one to five microns in size are plentiful. On the clinical side the case waits to be fully established; post-mortem evidence has not been forthcoming and X ray examinations are yet to be made. Now that the existence of this occupational disease has been suggested by statistical and mineralogical evidence clinical and pathological findings will doubtless follow, and the attention of technical advisers should be directed to eliminating the dust risk from the industry. The report takes cognisance of various other social conditions, such as housing, wages, and geographical location, and is thereby the more thorough; it contains two puzzling tables headed "proportionate mortality," in addition to more comprehensible figures, useful explanatory graphs, and excellent illustrations of the slate industry.

THE PRISON PSYCHOSES

FROM time to time in convict prisons examples are seen of certain morbid mental states which have been described as distinct disease forms under the name of "prison psychoses." These have been the subject of much inquiry, but, on account of the variation in the material which was available and in the conditions under which the studies were made some confusion of thought appears to have arisen as to what may or may not be regarded as belonging to this class of mental disorder, and whether, in fact, the classification is not redundant. In a recent paper,[1] published with the sanction of the Directors of Convict Prisons in England (although it does not necessarily represent their views), Dr. H. T. P. Young defines these states as "special types of mental reactions developing upon conflicts which arise as the result of imprisonment, and possibly from the shock attending the criminal act, trial, and conviction." He is careful to point out that in order that the existence of a separate and distinct disease may be demonstrated, it is essential that all those cases in which the chief external cause cannot be attributed to the effect of prison surroundings should be eliminated. This, in his study, he has endeavoured to do, considering as strictly eligible for inclusion in the group as defined only those persons of whom no history of mental or nervous disease is known apart from their prison records. As the result of his inquiry, Dr. Young finds that there is such a condition as a true "prison psychosis"; that its characteristics are observable both in first offenders and in recidivists; that, as a rule, its development is not rapid, usually a period of 6 to 18 months being required; that the condition appears to form a connecting link between the anxiety neuroses of a traumatic origin on the one hand and systematised delusional insanity on the other, bordering on the former more especially in first offenders who temporarily have lost their capacity to realise the full responsibility for their crimes and on the latter in recidivists whose anti-social feelings are developed more strongly, and whose facility in projecting their guilt appears to be more pronounced.

The material upon which these "Observations" are based consists of male convicts serving terms of penal servitude of three years and upwards, and of habitual criminals undergoing sentences of preventive detention; they belong to many races and to all grades of society, and they vary in intelligence and in educational attainments, while all the more serious forms of crime are represented. Among approximately the 300 convicts who had been placed under special mental observation, there were 19 cases in which these disordered states of a prison type were observed. This number does not include others whose symptoms bore the stamp of their environment, but in whom the disorders themselves varied but little from those to be seen in other situations and under other conditions. Of these 19 cases, five were certified as insane, and the remainder discharged from the prison hospital after periods of observation varying from a few weeks to several months When compared with their equivalents in the general community, they were relatively inferior in physique, in none of these cases were signs of tuberculosis, or a positive Wassermann blood reaction found, septic foci, however, were rarely absent The grosser sequelæ of encephalitis lethargica were not detected, nor was any connexion found in the cases examined between febrile conditions of short duration, such as influenza, and the onset of mental changes Although no biochemical tests were done, the routine physical examination revealed no gross changes in the thyroid gland, but instances of mild hypothyroidism were seen in some of the cases in which chronic infections incurred Apart from those prisoners in whom no psychopathic taint is known to exist, there is at Parkhurst, where this inquiry was conducted, a small group of men, forming about 5 per cent of the population of the prison, who, because of some distinct but uncertifiable mental abnormality, have been brought together from all convict stations for special mental observation and treatment, as well as all those whose mental state has given rise to doubt as to their fitness for ordinary convict conditions

[1] A Report of an investigation into the alleged high mortality-rate from tuberculosis of the respiratory system among Slate Quarrymen and Slate Workers in the Gwyrfai Rural District. W. T. Wade. Welsh Board of Health. Ministry of Health. Report No. 38. H.M. Stationery Office. 1927.

[1] Observations on the Prison Psychoses. By H. T. P. Young, M.B., Ch.B. Edin., Medical Officer, H.M. Convict Prison, Parkhurst. Reprinted from the Journal of Mental Science, January, 1927.

The observations and conclusions in this paper, therefore, refer to a population which is, in part, especially selected, and do not represent the conditions at other convict prisons This must be borne in mind when comparing this paper with previous writings on this subject In their " History of the Prison Psychoses," Nitsche and Wilmanns ably have summarised the more important of these earlier publications From them we learn that Reich, Moeli, Ganser, and others reported on insanity chiefly among those awaiting trial; that Rudin, Birnbaum, and Bonhoffer relied on observations which they had made after the cases had been received into a clinic; that Kirn's material consisted of short-term petty offenders who had been in solitary confinement, and Gutsch's patients developed disease when undergoing the same punishment; that Sommer inquired into the cases of men who had been transferred from prison to a criminal lunatic asylum, and Delbruck, who was, perhaps, the first of the investigators in this field, was in charge of a prison containing a large proportion of convicts who had been sent there from other institutions because they were not amenable to discipline, a fact which, as Dr Young points out, is suggestive of mental abnormality of some standing Few of these observers, not excepting Siefert, had access like Dr Young to cases of long-sentence prisoners in their own peculiar surroundings and when the disease was in its earliest stages

THE OXFORD OPHTHALMOLOGICAL CONGRESS

THE seventeenth annual meeting of the Oxford Ophthalmological Congress is to be held from Thursday, July 7th, to Saturday, July 9th, and an interesting programme has been arranged The sessions are to be held in the Department of Human Anatomy in the University Museum, and on Thursday, at 10 A M, the opening address will be delivered by the Master, Mr Philip Adams, after which Dr William H Wilmer (ophthalmologist-in-chief to the Johns Hopkins Hospital, Baltimore) will open a discussion on the Results of the Operative Treatment of Glaucoma Amongst those who will take part in this discussion are Prof Felix Lagrange (Bordeaux), Mr T H Bickerton (Liverpool), Mr A L Whitehead (Leeds), Lieut-Colonel H Herbert (Brighton), Mr Malcolm Hepburn (London), Lieut-Colonel R E Wright, I M S, Dr C F Bentzen (Copenhagen), Prof J Szymanski (Wilno), Dr T Harrison Butler (Birmingham), Mr R Davenport (London), Mr J Hern (Egypt), and Dr L Preziosi (Malta) The Doyne memorial lecture will be delivered on July 8th by Prof K K Lundsgaard (Copenhagen), his subject being the Pneumococcus in Connexion with Ophthalmology. At other meetings there will be numerous addresses and communications dealing with research and clinical practice The annual dinner of the Congress will be held on Thursday in the hall of Keble College, where members are offered accommodation A full programme of the arrangements may be had from the hon secretary, Mr Bernard Cridland, whose address is Salisbury House, Chapel Ash, Wolverhampton

A CARNIVOROUS RACE.

IT is generally believed that much renal and circulatory disease is due to impairment of nitrogenous metabolism by a diet too rich in animal protein, and it is therefore interesting to read an account[1] of some research undertaken by Dr William A Thomas on the Eskimos of Northern Labrador and Greenland, who subsist exclusively on fish and meat He derived his information from personal examination of the natives, and from the records and knowledge of the Danish physicians The hospitals of Greenland are excellent, and Dr Thomas had access not only to laboratory facilities but also to statistics covering many years The diet consists of whale, walrus, seal, caribou, musk ox, hare, polar bear sea-birds, and fish—all preferably eaten raw The Eskimo actually eats very little fat, but uses it for fuel, he prefers the red meat and liver, eating the entrails in time of scarcity The results of the inquiry showed no unusual prevalence of either cardiovascular or renal disease The average blood pressure of 142 adults was 129/76, and the highest was only 170/100 In this series albuminuria was found in 12 persons, of whom only three had a systolic pressure of more than 140, the other nine had moderate amounts of serum-albumin Two of the three who had both hypertension and albuminuria had casts in the urine and casts were also found in the urine of two of the remaining six who had hypertension only, and in three of the nine who had albuminuria without hypertension Nephritic œdema was seen in only one subject Of nine persons over 60 years of age only one had any albuminuria These natives lead lives of great physical activity and hardship, and seem to be quite capable of dealing with their high protein diet It is also remarkable that in carnivorous Greenland both scurvy and rickets are unknown Children are suckled until they are 4 or 6 years old and can eat meat In Labrador, however, where civilisation has trained the natives to buy cereals and dried and canned provisions, Dr Thomas notes that scurvy and rickets are universal The abundance of summer sunlight seems to give no effective protection against the latter disease The explanation may be that fish, and fish-eating animals, contain much vitamin C, as well as A, in their tissues Its source is presumably the marine vegetation on which the fish feed Stefansson, the explorer, was the first to propound the theory that a white man could find sufficient animal food in the polar seas to keep him in good health, and he had the courage to stake his life on it It is probable, Dr Thomas thinks, that most healthy white men could quickly adapt themselves to the natural carnivorous diet of the Eskimos, the raw skin of the white whale is an antiscorbutic as efficient as orange juice or banana What he must resist, apparently, is the temptation to eat polar bear's liver, as for some reason this is very poisonous

POST-MORTEM CIRCULATION

DR R Eisenmenger a specialist in physical therapy at Vienna, has succeeded in producing artificial circulation of blood in the human body after death[2] An air-pump[3] placed over the abdomen produces positive and negative pressures of 40 to 60 mm of mercury, these pressures alternating at the usual rate of the respiratory rhythm Positive pressure drives a certain amount of blood into the heart, where it is retained by the valves while negative pressure is refilling the abdominal veins and when this action is repeated the heart is overfilled and blood is driven on through the lungs The fact of circulation is proved by inserting a cannula into the proximal end of the divided median basilic vein, through which it is found a litre of salt solution at a pressure of one metre of water will enter the circulation within half an hour In the case of a woman of 40, who fell into the street from the third floor and was brought in dead, Dr Eisenmenger's apparatus was applied four hours after death, and during the half hour required for the litre of salt solution to enter the vein, the previously blanched face became cyanotic, blood began to ooze out of the distal end of the cut vein and from the site of a compound fracture, and the jugular veins showed definite oscillation in fullness Dr Eisenmenger recalls the observation of Prof Jellinek, of Vienna, that by the Sylvester method of artificial respiration a difference of pressure is produced between artery and vein in the cadaver, though this difference is too small to overcome the resistance in the capillaries He has no doubt that by his own method complete circulation is obtained and that blood penetrates the coronary vessels and those supplying the respiratory centre By this means, he considers, the heart may be mechanically stimulated without any dangerous incision in the abdominal wall, and therapeutic substances can be brought into the circulation by transfusion Dr Eisenmenger hopes that his observations will bring new interest into the study of attempts to restore life in the apparently dead

[3] Ibid, 1924, No 15

FROM July 25th to 28th the Section of Neurology of the Royal Society of Medicine is to hold a combined meeting in London with the American Neurological Association On Monday, July 25th, at 9 P M, there will be a reception at the House of the Society and the following day will be devoted to short papers On Wednesday a discussion on the Cerebellum will be introduced by Dr F Tilney, Dr H A Riley, Dr L J Pollock, Dr L E Davis, Dr A J Mussen, Dr T H Weisenburg, and Dr Harvey Cushing On Thursday the subject of discussion will be Sensory Disorders in Organic Disease of the Nervous System, the first speakers being Prof J S B Stopford, Dr Wilfred Harris, Dr Gordon Holmes, and Dr Kinnier Wilson At 5 P M on the same day Dr Charles L Dana will deliver the Hughlings Jackson Lecture, and in the evening there will be a banquet Fellows who wish to read papers or show cases at the meetings are invited to communicate with Dr W J Adie, secretary of the Section of Neurology

---

CONFERENCE ON MATERNITY AND INFANT WELFARE

A conference is to be held, under the auspices of the Central Council for Infant and Child Welfare, in the Great Hall of the British Medical Association, Tavistock-square, London, W C, from Tuesday, July 5th, to Friday, the 8th Amongst the societies and organisations to be represented will be the Maternity and Child Welfare Group of the Society of Medical Officers of Health, and members of the medical profession, outside the society, will be welcome to attend its meetings and to express opinions On Thursday, July 7th, at 10 30 A M, the subject of discussion will be the Workings of the Maternity and Child Welfare Act, 1918, and some Indications for its Future Development Lieut -Colonel F E Fremantle will give a general survey of the position, Dr J A Stephen will speak on the Provision of Observation Wards and Hospital Beds for Infants and Children under School Age, and Mr Harry Evers will deal with the Provision of Further Beds for Maternity Cases The afternoon session on the same day will be devoted to Respiratory Disease as a Factor in Infantile Mortality, and Measures Necessary for its Nursing and Treatment, Dr A S M MacGregor, Dr H H Chodak Gregory, and Dr Kerr Simpson will take part in the discussion The full programme of the Conference, in which a large number of medical questions are down for discussion, may be had from the Secretary of the Central Council at 117, Piccadilly, London, W 1 A number of social functions have been arranged, and railway facilities are offered to members

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXXIX

THE TREATMENT OF URTICARIA

WHEN confronted with an urticarial rash it is essential to realise that urticaria is not a disease sui generis, but is merely a symptom, that it may be produced by a variety of causes, and, furthermore, that there is no specific remedy Therefore, if successful treatment is to be anticipated, a detailed history must be elicited and a thorough physical examination of the patient undertaken It is often too readily assumed that urticaria is the outward manifestation of a food poisoning, and that some rather unusual article of diet taken within a short interval of the attack is responsible for the condition Certainly no one will deny that food proteins do in a large number of cases cause the rash, but experience has taught us that in many incidences this is not so, and that the ætiology is more complex.

The Acute Attack

As is well known, this is often accompanied by more or less severe constitutional symptoms such as vomiting, diarrhœa, and a general feeling of malaise The rash is usually profuse and sometimes even bullous It may involve the mucous membrane of the lips, tongue, or glottis Fortunately the latter complication is extremely rare, but cases have been recorded in which tracheotomy has been necessary Such attacks undoubtedly do frequently follow the ingestion of some article of diet to which the patient is sensitised It is only necessary to mention some of the more common of these—i e, shell-fish, tinned meat, or fish in which putrefactive changes have occurred Should the patient be seen during the early stages and the severity of the symptoms warrant it, an emetic should be administered In all cases it is advisable to give a dose of calomel, followed by a saline aperient Prompt relief from the irritation and burning of the distressing rash may be obtained by the subcutaneous injection of 5–10 minims of 1 in 1000 adrenalin chloride During the first 24 hours it is desirable that water only should be given by the mouth Recovery ensues in a day or two and the patient may eventually be able to resume the ingestion of the offending article of diet, in other cases the unfortunate individual may have a recurrence, not only when the particular protein is taken, but he may have become sensitised to other proteins and pass into

The Chronic Stage

This is by no means always preceded by an acute attack The onset may be insidious, the wheals recurring at regular or irregular intervals It is this chronic stage of urticaria which exercises the skill and patience of the physician, for the duration may be measured in terms of weeks, months, or even years, and may be due to an embarrassing number of causes Irrespective of the cause, the lesions may be small and circular, closely resembling the wheal produced by the nettle sting, or large and irregular Some may be bullous, resembling those of pemphigus, or the œdema of a limb or other part may be so pronounced as to earn the distinctive name of angioneurotic œdema Whatsoever be the form or duration of the lesion, its cause is only likely to be ascertained if the examination be conducted in a systematic manner.

External causes —It is hardly necessary to state that the bites of certain insects may cause urticarial wheals, but it may not be generally known that an infection with scabies is sometimes responsible I can recall a case in which wheals had recurred obstinately for many weeks before the presence of this parasite was revealed It is interesting to note that few excoriations are as a rule found on a patient suffering from urticaria Sudden changes of temperature in a susceptible person will bring about the quick onset of the rash , both hot and cold baths have been known to produce it Certain articles of clothing may be the exciting cause, as may be also contact with various plants and chemical irritants When the offending agent has been detected and removed no further treatment is needed

Internal causes —Such varied examples as blood diseases, diseases of the female generative organs, boils, rupture of a hydatid cyst, have been quoted as occurring concomitantly with an urticarial rash Infrequent as such causes may be, they serve to emphasise the fact that urticaria should be regarded as a symptom and not as a disease

Recently many apparently authentic cases have been published in which there has been cessation of the rash subsequent to removal of some septic focus The presence of intestinal parasites may account for recurring attacks, and some subjects have such a predisposition to this reaction of the skin that emotion and other psychical disturbance may be followed by wheals An example of this was recently described in a continental journal[1], a woman complained that contact with silk, but with no other material, caused the rash to appear at the site of contact A test apparently verified her statement, yet when cotton material was substituted for silk, without her knowledge, the rash still appeared

Food Proteins

There remains for discussion what is probably the principal rôle in the production of urticaria—namely, absorption from the digestive tract To enumerate the various food proteins which have been known to cause urticaria is outside the scope of this article ; the best plan is to suspect all The protein sensitisation tests introduced during the last few years have not given the assistance that was anticipated from them Patients will often be found who give a positive reaction to one or more of these protein extracts, yet when the particular food is omitted the rash continues The tests appear to show that the patient is hypersensitised but do not necessarily indicate which particular food he should avoid A more serviceable method is one for which I believe we are indebted to Sir Norman Walker This is as follows The patient is instructed to keep a daily ledger On the left hand page a detailed account of the meals and events of the day is written, whilst on the opposite page the time and the appearance of the rash is noted First one common article of diet is omitted for several days and then another until all in turn have been excluded If this plan is conscientiously carried out valuable information is obtained, and the noxious substance may possibly be ascertained It is advisable to impress upon the patient that if, for instance, he is to omit eggs, he must avoid cake or pudding which contains egg albumin or yoke, however small the quantity A more rapid method of excluding food protein as a possible cause is to confine the patient to bed for three days and allow milk diet only If the rash, in spite of the restriction, continues, rice water should be substituted for milk The method is rigorous, but a patient suffering from a severe recurrent urticaria can well afford to put up with discomfort if the ordeal gives promise of relief

In the fortunate event of the noxious substance being detected, the remedy is obvious ; however, it may be very inconvenient to omit from the dietary common articles, such as milk or eggs In such instances desensitisation may be attempted

Desensitisation may be accomplished in one or two ways Commencing with a minute dose, in the case of milk a few drops, the amount is increased daily if tolerance is maintained , the second method is to bring about anti-anaphylaxis by giving a small quantity of the particular food one hour before the meal containing it is taken Should attempts to ascertain the ætiology fail, as unfortunately is too frequently the case and the rash persist, then more or less empirical remedies have to be relied upon

Empirical Remedies

Calcium salts have had a long innings, but in my experience the results have been singularly disappointing, so have also the somewhat older remedies ichthyol and quinine Aspirin will sometimes give temporary relief On the assumption that urticaria is a manifestation of the anaphylactic state, peptone has been recently advocated by French dermatologists. The dose recommended is 0 5 g taken one hour before each meal Since urticaria has been noted in cases of hypothyroidism, thyroid extract has been lately prescribed as a remedy , one author, indeed, goes so far as to proclaim it a specific In two recent cases, a young girl and a middle-aged woman, in which I have tried it, there has certainly been a gradual and lasting improvement Auto-hæmotherapy is worthy of a trial should other methods fail , 10 c cm of blood is withdrawn from a vein and rapidly injected intramuscularly with the usual precautions into the buttock. This is repeated twice weekly

Of *local applications* for the relief of the itching, lotions are preferable Of these the usual lotio calaminæ with the addition of a small quantity of liq plumbi subacet or carbolic acid is useful, but many patients find the domestic remedies of vinegar or lemon juice the most efficacious At night the chosen remedy should be placed in a shallow dish by the bedside so that it may easily be applied if necessary.

Lichen Urticatus

Urticaria in the true sense of the word is not frequently encountered in children There is, however, a relatively common disease known as papular urticaria or lichen urticatus, which is probably closely related to urticaria It is distinguished by the appearance of a minute papule which appears in the centre of a small wheal of varying shape and size. The complaint causes very great distress to both the child and its unfortunate parents, for it is intensely irritating and may be accompanied by a secondary impetiginous infection It is more prevalent during the summer months than during the colder months The ætiology is obscure and the treatment unsatisfactory I have noted the curious phenomenon that the sufferers recover immediately they are admitted to hospital even although no treatment of any kind be given , the rash returns after their discharge. Based on this experience numerous experiments on the influence of various diets have been made, but the cause of the disease remains a mystery. The experiments referred to pointed to heat being the most active exciting cause The parents should therefore be warned against allowing the child to be over-clothed, particularly at night For the same reason the child should neither be undressed in front of a fire nor placed in a hot room It is customary to restrain children suffering from some skin diseases by splints or bands In this disease this would seem to be unnecessary cruelty, for scratching appears to afford relief to the sufferer and does not prolong the course of the disease

Removal to another house may be tried if feasible, for prompt recovery often follows A Nottingham patient, seen by the writer, only had the complaint when staying with his grandparents in Sheffield, whilst another boy was quite free when away at school at Worksop, yet always had the rash on returning to his home in Sheffield In my experience no internal remedy is of any real value The following have their adherents *calcium lactate, vinum antimoniale* and, recently, peptone, one hour before meals The child should be carefully examined for foci of infection and particularly for the presence of threadworms Locally the following application will be found serviceable —

Liq carbonis deterg	30
Pulv amyli Talci	āā 40
Glycerini	20
Liq plumbi subacet	4
Aquæ	200

RELATIONSHIP OF PHYSIOLOGY TO MEDICINE AND SURGERY.

An Address to Members of the Inter-State Post-Graduate Assembly of North America, delivered at Edinburgh on June 6th 1927,

By Sir EDWARD SHARPEY-SCHAFER, F.R.S.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF EDINBURGH

Physiology forms the basis of Medicine and Surgery. Until lately it was known in this University as the Institutes of Medicine which, being interpreted means the Foundations of Medicine; the term is still used in Trinity College, Dublin.

Literally physiology means the science of nature, but is now restricted to mean *living* nature. It is therefore the science of life, also known as biology. Animal physiology is the science of animal life, human physiology that of human life. Physiology must be studied in living organisms or in living—i.e., surviving—parts of the organism, such as separated organs, or tissues, or isolated cells. As with every other branch of science it can only progress by experiment and, since it deals with life, experiments can only be made on the living subject. Some experiments can be and are made on man. Every patient must always be the subject of experiment and in that sense every doctor has the opportunity of advancing the knowledge of physiology. We shall, in fact, see that physiology owes much to the observations and experiments of clinicians. But most experiments in physiology cannot be carried out on the human subject; they must be performed on the lower animals, and the results—so far as possible—transferred to man. Hence the necessity for "vivisection." Vivisection is performed every day by the operating surgeon upon his human patients, but only arouses indignation amongst unreasoning people when it is performed upon animals for the benefit of humanity. Only those who are callous to human suffering can reasonably contend that experiments upon living animals should be put a stop to because it *may* involve the infliction of pain upon them. It involves no more pain than operations upon man—usually none at all—since the animal under operation, like a subject under surgical operation, is kept anæsthetised during the whole time. An animal is generally killed while still anæsthetised. Even if the experiment requires that it should be kept alive for the subsequent result of the operation to be observed, it will suffer no more than the surgical patient recovering from an operation—indeed, in most cases far less. Operation on or inoculation of the lower animals is the only way we have of extending our knowledge of medicine and surgery in man; unless we are to make our experiments upon man himself, which few would, I think, contend to be justifiable, even if, as would indeed be the case there were men and women brave enough to offer themselves as the subjects of experiment. In the investigation of diseases which are peculiar to man it is sometimes necessary that inoculation should be carried out on man, and there have never been lacking doctors who are willing to take the risk of serious illness or even death in order that the ætiology of such affections should be cleared up. Self-sacrifice of this kind is as heroic as that of the battlefield and is no less deserving of recognition, although it rarely, if ever, receives it.

Ancillary Sciences

For the study of physiology a prior knowledge of three other sciences is essential. These are physics, chemistry, and anatomy. The application of physics to physiology or biology is termed biophysics; that of chemistry, biochemistry. The one deals with the physical changes associated with the functions of the living body, the other with the chemical changes. But we cannot understand the working of a machine without a knowledge of its structure, and this is where anatomy comes in. Further since the functions of the body are actually performed by the living cells and tissues composing it, the microscope becomes an essential instrument to the physiologist, who needs to observe both the microscopic structure of the living cell and the changes it undergoes as a result of activity. On this account histology or microscopic anatomy has in this country always been taught along with physiology, although it has been the custom in Germany and America to associate it rather with the teaching of anatomy. But since no problem in physiology can be considered completely solved until it is brought down to the bed-rock of the changes occurring in the living cell, the importance of the microscope as an adjunct to physiological methods becomes apparent. This is beginning to be recognised in the United States, witness the microdissection methods of Chambers of New York, the observations on renal activity of Richards of Philadelphia and the interesting results obtained with surviving tissues by Harrison of Yale, and by Carrel of New York. The physiologist who neglects the use of the microscope eventually finds himself in a blind alley beyond which he can make no further progress.

If it is true of physiology that the microscope is an essential instrument of investigation it is still more evident for the daughter sciences of pathology and bacteriology in which all the methods of physiology are employed and for both of which the microscope is a first necessity. And since at the present day the progress of medicine hinges on those two "ologies" it is scarcely too much to aver that the microscope is the most important instrument for advancing our knowledge of medical science. No one understood this better than the great Lister, who expressly tells us how invaluable for his later researches he found the early training in the use of the microscope which he obtained from his father, to whom, as is well known, we owe the modern form of this instrument.

Rational Medicine and Surgery

In considering the relations of physiology to medicine we must recognise and accentuate the fact that medicine is no longer an art, but has developed into a science. That a good deal of empiricism remains attached to its practice is inevitable by reason of our ignorance of the causation and exact course of many affections; until these are known there can be no rational treatment of them. But all patients look for treatment of some sort, whether rational or not; they naturally expect you to do something for them if only because that is what they pay you for. Your own experience or that of your teachers may have shown that, whatever the reason for it, a particular line of treatment or the administration of a particular drug will alleviate the symptoms of a disease regarding which you know of no rational remedy, and you therefore employ that line of treatment, although you may be well aware that it is purely empirical. Regarding this we must bear in mind that empirical methods which have been constantly employed in past days (such for example as those referred to in the libellous epigram on Lettsom, "I physicks, bleeds and sweats 'em") are now abandoned as useless or harmful. But these abandoned methods were in their day recognised as efficient by the whole profession of medicine. We must therefore remember that such empirical methods as may be in fashion in our own time are liable to meet with a similar fate. Only if there is a scientific reason for any course of treatment can you justly repose confidence in it. A great advance has been made in the administration of drugs the action of which is much better understood than was formerly the case, so that their empirical use is being gradually relinquished. Even the laity is beginning to ask the reason for administering this or that medicine. And the great drug-manufacturing companies now not only have chemical but also physiological laboratories belonging to them in order that the medicaments they produce may be tested *and standardised by their action upon animals before* being sent out for the use of the profession.

Many cases, as we know, require not only a careful physical examination of the body, but in addition the chemical and microscopical examination of the urine, and in certain instances of the blood as well. It was no doubt a simpler proceeding to determine the nature of the disease merely by visual inspection, which need not have embraced the patient himself, but may have merely consisted of an inspection of his urine. You will remember how Falstaff sends his page to the doctor with a sample of urine in order that it may be "cast."

> *Falstaff.* Sirrah, you giant, what says the doctor to my water?
>
> *Page.* He said, sir, the water itself was a good healthy water, but for the party that owed it, he might have more diseases than he knew for.
>
> *King Henry IV., Act I, Scene II.*

At any rate the patient had no doubt as to the doctor's ability to effect both a diagnosis and a prognosis in this manner. But I do not think that the method would satisfy even the most confiding patient of the present day.

If Medicine now takes rank as a science, this is even more true regarding Surgery. Not that the *art* of Surgery will ever disappear, for after all is said about its scientific aspect the work of the surgeon will always be a form of handicraft, and in every handicraft there must be individual differences. Nevertheless no surgical operation can be undertaken without a knowledge of certain sciences. These deal respectively with (1) the structures to be encountered (anatomy), (2) the probable effects of the operation, immediate and remote (physiology), (3) the nature of the disease or injury (pathology), (4) the risk of contamination with micro-organisms (bacteriology); and (5) the *administration* of the anæsthetic and the after-treatment of the case, whether by drugs or *otherwise* (pharmacology and therapeutics). Of all these the surgeon must possess an adequate knowledge.

Beginning of Physiology.

The dependence of Medicine upon Physiology is evidenced by the fact that all forms of treatment were purely empirical before a correct conception of physiology was introduced—i.e., before the study of physiology, in the modern sense of the word, had really begun. This beginning dates from almost exactly 300 years ago. Harvey had been teaching his doctrine of the circulation of the blood for several years in lectures to the Royal College of Physicians of London, but he did not give it to the world until 1628 when his immortal work on the heart and circulation was published. This book—the original edition is rare, the University of Edinburgh is fortunate enough to possess a copy—must be regarded as indicating the beginning of physiology as we understand the term. For until the action of the heart and the course of the blood was comprehended no clear notion regarding the functions of any part of the body could be had; everything was guess-work. The famous epitaph composed by Pope on Newton,

Nature and Nature's laws lay hid in night
God said, "Let Newton be" and all was light,

might equally well apply to Harvey so far as the living body is concerned. Until his time medicine was groping about in complete darkness, but as soon as his doctrine was enunciated light was *at once* thrown on the functions of the body and the foundation of physiology was laid. Although the evidences he adduced appear to us convincing, his doctrine was by no means at once universally accepted. So difficult is it for men to disabuse their minds of ideas which have long persisted and with which in their education they have become thoroughly imbued however decisively these ideas may have been shown to be erroneous! Nevertheless the foundation of scientific medicine was being *laid* at the same time, although many did not acknowledge it. It was indeed long ere the empiricism which characterised medicine was abandoned, nor, as we have seen, is it yet wholly given up. But with the growth and development of physiology and its daughter sciences medicine has become gradually built up into the imposing edifice of which to-day it is constituted.

It is not with one aspect only of physiology that the medical man of to-day is interested. For only an increased knowledge of the function of each several organ renders advance possible in the treatment of diseases of that organ. This is well illustrated by the work of Bernard on secreting glands, of Ferrier and others on the functions of the brain, of Pavlov on the digestive organs, and by more recent discoveries regarding the influence of internal secretions on many functions of the body. Perhaps the most striking illustration of the direct application of physiological research to medicine is to be found in the recent discovery of insulin, which has enabled the life of the diabetic to be prolonged to the normal limit and has restored him not only to health but to a condition of usefulness and freedom from anxiety which was impossible to be achieved by dietetic treatment alone.

Training of Medical Men.

Apart from the effect the advances in physiology have had in promoting corresponding advances in medicine, work in physiology affords the best possible training for the practising physician or surgeon. Many instances might be adduced of the effects of such training upon individual physicians *both* in the past and in the present. As regards surgeons it has been customary to assume that what they chiefly require is an accurate knowledge of anatomy, although I well remember one of my own teachers—an eminent surgeon but of the slap-dash kind—whose favourite advice to the student was "Don't let your anatomy spoil your surgery." I hope we most of us *allowed the advice to pass unheeded*; but the idea that only a precise knowledge of anatomy is *required by the surgeon was long prevalent and* is, if possible, even more unsound. For it must be remembered that every surgical case is always in the first instance a medical case, and requires for diagnosis and treatment all the methods of the physician as well as the special methods of surgery. These methods are based on those of physiology, it therefore follows that a training in physiology is as important for the surgeon as for the physician. The effect of such training on the development of their science is well illustrated by the career of many surgeons of the present day. But by far the most eminent example is the case of Joseph Lister. Although it is not very generally known Lister's training was mainly physiological, and all his early work was of a purely physiological character. If he had not developed into the greatest surgeon of all time, he would have become a great physiologist. His physiological work is characterised by an extraordinary accuracy of observation and ingenuity of method, and it was the experience he *gained* in his physiological researches which enabled him to carry to the triumphal termination we know the investigations which led to the discovery of the principles of antisepsis, on which, in its more modern form of asepsis, the whole practice of modern surgery is based.

The Reciprocal Obligation.

I have said perhaps enough to indicate the obligations of medicine and surgery to physiology. It would be possible to expatiate on this theme to any extent, but I wish to deal very briefly with another aspect of the subject of this address, and that is the obligations of physiology to medicine and surgery. In this I shall restrict myself to examples drawn from the internally secreting organs partly because to do anything else would occupy far too much time, partly because it is the subject with which I am personally most familiar.

In the first place then, I would remind you that the discovery that the suprarenal capsules (adrenals) possess any function at all was due to the clinical observations of Dr. Addison, of Guy's Hospital, London, who, I may remark in passing, received his medical training in Edinburgh, but, like many another Scot, migrated south and stayed there. Addison in 1855, described the affection which bears his name, and showed it to be invariably accompanied by destructive disease of the suprarenal capsules, and to be as invariably fatal. This announcement led to a number of experiments on animals to determine whether the ablation of these organs was equally fatal in them. The question was answered in the affirmative by Brown-Sequard, and his verdict is now generally accepted. The attention of the physiologist having been thus directed to the suprarenal capsules they have ever since remained objects of interest not only to him but also to the physician. If you look through any file of physiological literature you will find that relating to the suprarenal capsules to occupy a bulk entirely disproportionate to the size of these small and apparently insignificant structures.

As a second example I will take the discovery of the functions of the thyroid and parathyroids. It was noticed about the year 1883 by certain Swiss surgeons (Theodor Kocher and J. L. and A. Reverdin) that after surgical removal of the tumour formed by the enlarged thyroid in cases of endemic goitre the patients became apathetic, their mental processes were dulled, and in the worst cases they lapsed into a condition indistinguishable from idiocy. This condition was accompanied by a peculiar œdematous affection of the integument and by other physical signs which I need not further specify. Some of the operated cases also exhibited the symptoms of the affection known as tetany. This was also at first ascribed to the loss of the thyroid, but is now known—thanks to the physiological work of Gley—to be due to the inclusion of the parathyroids in the extirpation. Some time before—namely, in 1874—the clinical observations of Sir William Gull in London showed the existence of a syndrome characterised by atrophy of the thyroid and having the same symptoms as were later shown to be caused by surgical removal of that organ: to this disease the name *myxœdema* was given by Ord. Subsequently it was found that grafting portions of thyroid after extirpation of the whole gland would prevent the characteristic myxœdematous symptoms, and still later that subcutaneous injection of thyroid juice or extract (Murray) or even administration of thyroid by the mouth would entirely combat the effects of thyroid removal or atrophy in man.

These clinical observations led—like those of Addison on the suprarenals—to physiological experiments upon animals. The experiments showed that loss of the thyroid is in most cases at all ages (in young animals always), productive of a condition of depressed mentality—so far as it is possible to determine this in animals—similar to that which occurs in man, as well as most of the other physical symptoms which had been described clinically. It was further found that the condition could be entirely obviated by grafting portions of thyroid and by subcutaneous or oral administration of the gland or its juice. And it has recently been shown (Collip) that parathyroid extract is effective in combating the symptoms of tetany caused by removal of parathyroids. Thus all the physiological work on the thyroid and parathyroids had its origin in clinical observations.

My third illustration is derived from the pituitary body. About 40 years ago the eminent Paris physician, Pierre Marie, gave a description of a peculiar syndrome characterised by the appearance of greatly enlarged extremities—hands, feet, and face (although the hypertrophy which causes this enlargement affects the whole osseous and connective tissue structure of the body). To this affection he gave the name acromegaly, and showed that it is always associated with tumours of the pituitary body. Those tumours he supposed to be destructive, and to test this hypothesis physiologists set to work to destroy the pituitary in animals in the expectation that they might show a similar syndrome. But they found that the effect was exactly the opposite; if the destruction were effected in a growing animal it ceased to grow. Evidently, then, "the boot was on the other leg", the tumour was not a destructive one but an adenoma—i.e., an enlargement of the gland itself. And this supposition is corroborated by the observation that "giants" are subjects who, during the process of growth, have undergone enlargement of the pituitary body—at least of its anterior part; this enlargement has produced the same effects as those seen in acromegaly, with the addition that the long bones have grown in length owing to the fact that the enlargement of the pituitary has occurred before the diaphysis and epiphysis of these bones had undergone ankylosis. Since Marie's observation the attention of physiologists has been directed to this minute organ, the functions of which were until then unknown. And although much remains to be elucidated a great deal has been discovered respecting these functions not only in connexion with growth but—as regards its posterior lobe—with the activity of involuntary muscle (especially of the heart, blood-vessels, and uterus), with the functions of the kidney, and with those of many other organs of the body. Indeed, the literature of the present day relating to the pituitary body is probably greater in amount than that relating to any other subject, not even excepting the thyroid and the suprarenals.

Advance of Knowledge

The obligations of physiology to surgery cannot be evidenced by mere illustrations such as those I have given for Medicine. The progress of Physiology at the present day goes hand in hand with the progress of Surgery; they are mutually interdependent. The physiologist employs in his experiments all the methods of modern surgery and, as surgical technique improves, each improvement is adopted by the physiologist. And in advancing his subject the experimental surgeon becomes a physiologist and advances physiology at the same time. No sharp line of demarcation can be drawn between the two subjects; nor, indeed, between any of the branches of science associated with medicine. In one direction Physiology borders on Pathology; in another on Pharmacology; in another on Chemistry; in another on Physics; in another on General Biology, both of animals and plants. It is indeed a mere axiom that no branch of science can be properly dealt with unless its relation to others is taken into account, and to none does this more directly apply than to the mutual relationship of Physiology and Medicine.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

War on Mosquitoes

ACCORDING to a report recently issued by the Ministry of Health, malaria is claiming a considerable number of lives because the protective organisation is inadequate. The yearly average of deaths caused by the disease is nearly 5000 and about 100 000 persons are infected. They are mostly of the working-classes, and especially agricultural labourers, who are not protected at all, whereas industrial workmen, being under the control of the sickness insurance offices, come up from time to time for medical supervision. According to Dr. Banu, Secretary of the Ministry of Health, the greatest obstacle to efficient prophylaxis is the lack of physicians in the counties most infested with malaria. This grievance is to be remedied by offering good salaries to young doctors willing to settle in these districts. A central bureau will be established in Bucharest, and here the various problems will be thoroughly studied. In every county in the infested district a laboratory is to be established, adequately equipped and with a competent medical staff Here the blood of all the people in the neighbourhood will be examined As a remedy quinine will be administered, in the form of blue tablets, which will be distributed free to all who need them To help in the destruction of mosquitoes the Ministry proposes to stock the breeding-places with certain kinds of fish which, it is said, are able to destroy the larvæ and eggs. Extensive experiments have been made with these fish in America, Italy, and Jugoslavia, with satisfactory results The fish, though very small, are extraordinarily voracious, and each of them is capable of destroying about 1000 larvæ a day Dr Mezinescu, director of the State Institute of Hygiene, has brought a great quantity of the fish from Jugoslavia and is going to breed them in his laboratory. When he has a sufficient number at his disposal he will distribute them in the Danube swamps

How to Deal with a Typhoid Epidemic.

In some remote regions of the Near East there are still great masses of people who refuse to recognise the advantages of hygiene and continue to prefer superstitions to sanitation The inhabitants of Huszt, a small rural town in Russinsko, recently revived an old method of driving away typhoid The situation in the town was threatening, inasmuch as within two weeks eight patients had died of the disease, and there were about 40 others ill with it The epidemic naturally caused great consternation among the people, and they feared lest it should spread and carry off the principal townsmen In this extremity they recalled an old Jewish tradition—the town is mainly inhabited by Jews—according to which, in case of raging epidemic, a particular form of wedding ceremony has to be held in a cemetery The triumph of life, it is said, banishes the danger of death. The Jewish community yielded to the representations made and held the ceremony as required, the bride was a servant girl of 17 and the bridegroom a labourer of 26 Some 4000 spectators attended The rabbi walked three times round the cemetery with the couple declaiming a special prayer According to tradition only married men and women were allowed within the fences, the rest of the spectators having to remain outside

Advertising by Medical Men.

In recent years public health and sanitation have undergone very radical changes in Rumania The establishment of the Ministry of Health in 1924 opened a new era for the health of the countryside, which in former times was much neglected as regards the supply of doctors, hospitals, and dispensaries A reminder of these times is the unethical custom—which still prevails, though sporadically—of open advertisement by doctors in the daily papers In most of these may be found small announcements to the effect that X, who graduated at Paris, is a specialist in internal diseases and syphilis, or that Y is a graduate of Vienna University and a specialist in children's diseases So far the Rumanian Medical Association, which is very busy with the organisation of its provincial branches, has been unable to deal with this abuse, but one of its main objects is to fight against it

Not long ago a certain physician complained to the editor of a medical monthly that he had been fined by the local health magistrate, under the Health Act, for having advertised himself in a manner prejudicial to the medical profession Of course the editor, instead of taking his side, exposed his case (without giving away the name) in a leading article, and condemned him for expecting protection after so reprehensible an offence Furthermore, he called upon the health magistrates to study the advertisement pages of the newspapers and fine all medical advertisers according to their demerits Only this, it is considered, can stop the kind of advertisement which is still seen One doctor refers to himself as superspecialist; another promises the "radical and definitive cure of epilepsy," and even offers to make a contract authorised by the courts guaranteeing absolute cure to his patients Still more interesting is the advertisement of another medical man who "is in a position to cure acute and chronic diseases and to cure syphilis with three injections, radically"; whilst another provincial doctor has distributed leaflets from the air, promising cure for every conceivable disease and embellished by his photograph A new Bill is shortly to come before the Legislature, containing the following paragraph "Physicians, dentists, veterinary surgeons, pharmacists, and midwives are strictly forbidden to advertise in non-professional papers, this being contrary to the dignity of their profession It is forbidden to insert in newspapers, or on posters, or in leaflets, &c, statements intended to cause in the minds of sick people the belief that the advertiser is possessed of certain secret remedies which are capable of curing chronic diseases, which at present are regarded by medical sciences as incurable" When this Bill becomes law the lay journals will lose a large contingent of their regular advertisers, whilst the medical profession will gain very much in prestige and dignity

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Mince-meat

Mince-meat is one the staple forms of flesh consumed in Scotland, where it is more popular than in the South, and its use is as well understood as that of oatmeal used to be Under the Food Preservatives Regulations mince-meat must no longer contain any preservative In England this rule is absolute, in Scotland an exception is made for the months of June, July, August, and September, when the mince may be treated with sulphur dioxide to the extent of 450 parts per million Early in June a case was raised by the local authority of Clydebank against five butchers who were charged with contravention of the regulation The charge was abandoned on technical grounds, so no decision was reached, but it is interesting to note that the butchers still contend that this popular form of meat cannot be provided commercially without some form of preservative Before framing the regulations both the Ministry of Health and the Scottish Board of Health heard deputations on the matter and, as I have said, in Scotland an exception was made for the hotter months of the year It is too early yet to know what the experience has been where preservatives have been dropped In any butcher's shop in Scotland one may see the unnaturally bright colour of mince, as against the normal brown colour of wholesome meat of the same age The process of mincing, of course, results in the exposure of a vastly greater surface to bacterial invasion, and if conditions are not strictly aseptic the meat tends more readily to "go wrong" The remedy, surely, is not to arrest incipient putrefaction by preservatives, but to make the process of mincing and conservation more aseptic There is here a case for the extension of refrigerating methods

Students' Hostels

The University of Edinburgh has received another gift from Mr Thomas Cowan, the Leith shipowner. He had already given £30,000 and has now given another £30,000 to help in providing a residential hall for students to be called Cowan House The second gift is meant to help towards endowment Edinburgh has many women's hostels, particularly those at Liberton, where teachers in training are housed. They have been much visited and are run with conspicuous success But recently there has been a strong move towards providing hostels for men, and Mr. Cowan's handsome gift will be of great assistance

A Tuberculous Cow

It is satisfactory to find that the Diseases of Animals Act is being more rigidly enforced A farmer was fined £10 at a Stirling court for failing to give notification that a cow in his possession was suffering from tuberculous emaciation The butcher who sent the cow to a Stirling live-stock market was also charged and was fined £2 It is reported that he "only saw the cow once in the dark with the aid of a lantern" The Board of Agriculture Order is operating well and a large number of tuberculous cows are passing out of circulation, but before this Order can produce its full effect the negligent buyer needs to be taught an occasional lesson

David Livingstone

Many years ago I visited Blantyre, which used to contain some of the worst housing-groups in Scotland At that time it was proposed to remove the row containing the house where Livingstone was born All Scotland—at home and abroad—is awakening to the proposal that the house should be preserved as the birthplace of an Imperial pioneer It is perfectly possible to wipe out these rural slums without sacrificing that historic room and the success of the appeal has made this possible The Lanarkshire Education Authority, not without some grumbling, has decided that it was proper for the committee to approach the school-children through the schools for personal contributions to the memorial

Cruelty to Children

It is lamentable to read the reports of the local branches of the Royal Scottish Society for the Prevention of Cruelty to Children Year after year they produce a tale of cases dealt with that horrify the imagination with the amount of misery and social maladjustment revealed The Leith branch, for example reported that for 1926 209 cases (the population of Leith for this purpose is about 80 000) involving the welfare of 519 children had been dealt with as against 210 cases and 528 children for the previous year. Of the cases 150 were attributable to general neglect and 21 to ill-treatment and assault. There were eight prosecutions An inspector paid some 3500 visits of supervision and inquiry. This society is doing admirable work but obviously we are very far from the mastery of the conditions that make its efforts necessary. Leith is only an example of what happens in equal proportion elsewhere The Children Act was hailed many years ago as the Children's Charter, but there is still the same weary work to do, and the "Charter" does not seem to have made much difference. This is a problem that might fairly be investigated afresh.

DIABETES AS A FATAL DISEASE.

THE INFLUENCE OF INSULIN

The interest in the mortality from diabetes has redoubled since the early part of 1923, when its treatment by insulin was introduced, and stress has been laid in certain quarters on the fact that in females little or no reduction of the total death-rate from diabetes has occurred since the introduction of this treatment Publication of the Registrar-General's report for 1925 [1] now gives opportunity for study of the death-rates from diabetes for each sex, corrected or standardised so as to eliminate the disturbing factors of varying distribution of age and sex. When this has been done the highest male death-rates in 1916–22 are seen to have been 121 per million in 1916 and 101 in 1922, the rate falling to 81 4 in 1925 For females the highest rate was 98 in 1916, 97 in 1922 falling only to 94 in 1925 This course of events is made the subject of detailed analysis in the Registrar-General's report, the death-rates from 1911–25 for each sex being stated at various age-periods—0–5 to 75+.

The conclusions drawn are profoundly suggestive Comparing average death-rates 1901–10 and 1921–25, it should be premised that there was for males a substantial decrease of diabetes mortality at the ages 15–75, but only a slight decrease for females, and only at ages 25–55, "with large and progressive increase at later ages" The general trend evidently is very dissimilar in the two sexes.

Pursuing the comparison for each decade of life during the 15 years 1911–25, strange differences between the sexes emerge which may be illustrated for the ages 15–25, 35–45 and 55–65 by the following curves drawn from the table on p 47 of the report For other ages the report itself should be consulted. These curves show for males and females respectively the magnitude of the death-rate in each year 1911–25 in proportion to the death rate for 1901–10 stated as 100 Three sets of factors are regarded in the report as having had a possible influence on the course of these death-rates—viz, the partial deprival of food in various forms during the Great War, especially in 1917–18, the possible or probable excessive indulgence in sugar and other foods in more recent years, and the therapeutic use of insulin in the last three years 1923–25 As regards the war period the middle curves, for ages 35–45 in the diagram, suggest a definite influence of altered and reduced diet, and so do the curves for 55–65 The teaching of the curves for ages 15–25 may be regarded as dubious The experience of the last three years, with one exception, points strongly to the value of insulin as a means for reducing the death-rate from diabetes The exception

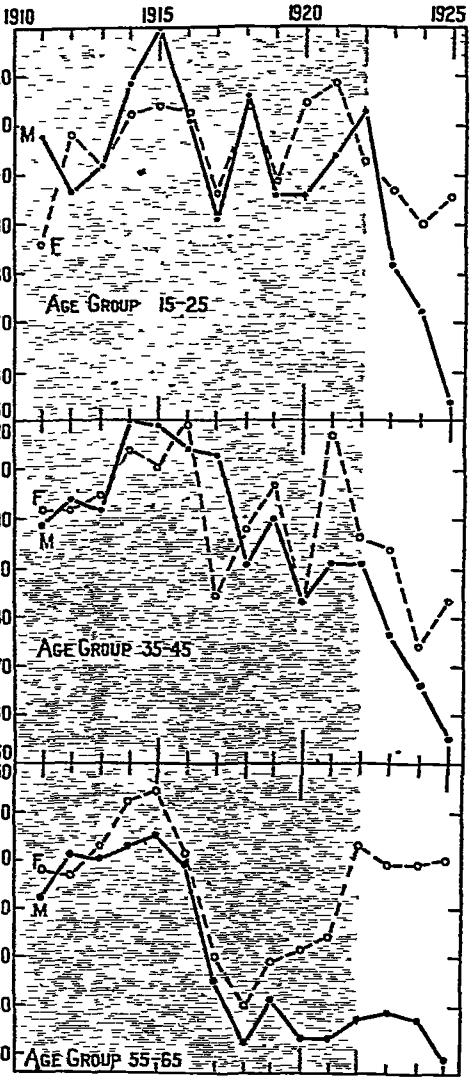

Chart showing the proportional death rate from diabetes between the years 1911 and 1925, of males and females, at various age periods M = Males F = Females The corresponding rate for 1901–10 is taken as 100. The shaded area ends with the discovery of insulin.

---

[1] The Registrar General's Statistical Review of England and Wales for the Year 1925 Text. H M Stationery Office 5s

is that part of the curve dealing with women aged 55–65. Why should this curve not have followed the general course, which can be seen in fuller detail in the diagram on p. 48 of the Registrar-General's report, and why should the general reduction in both sexes at ages over 55 have been so much less than that at earlier ages?

No conclusive answer is given in the report to these questions, nor is this possible, but the material suggests a widening of the problem for consideration. Has there been in recent years an undue reaction against the food restriction during war-time which would suffice to account for the failure at higher ages to secure the reduced mortality shown in the young? *This would raise the question as to whether deaths* from glycosuria in elderly people are rightly returned as due to diabetes, but whether wrongly attributed to hyperglycæmia or not, they must for many years to come be classed with diabetes, the result of pancreatic disease. The same problem has appeared in the United States, where also it has been suggested that over-eating in elderly people is largely responsible for the relatively unfavourable course of the diabetic curve at ages over 55. The question is one of which more will be heard.

MEDICINE AND THE LAW.

Mosquitoes as a Nuisance.

IN *what is stated to be the first case of its kind*, the sheriff court at Paisley has held that it is a nuisance within the Public Health (Scotland) Acts if a land-owner allows stagnant water to remain upon his land so that mosquitoes breed there in such numbers as to cause annoyance and injury to local residents. The action was brought by the health authorities of the county of Renfrew, and the court ordered the respondents to clean out the overgrown and stagnant ditches which had become the breeding-place of the mosquitoes.

It is rash for writers in England to offer any exposition of Scots law, but it may perhaps be assumed that the principles of nuisance are the same on both sides of the border. In England we have our own statutory nuisances defined under the Public Health Acts as from time to time extended. And, apart from statute, English common law treats as a nuisance a state of affairs which interferes with the health of the public. From the brief report of the Paisley case in the *Times*, it does not appear that the potential danger of mosquitoes as carriers of malaria was stressed; it was apparently the mere ordinary biting of the insects which annoyed the neighbours. If there were present the added menace to health which would exist in malarial districts, the legal nuisance would be even more clearly established. In England at common law we have known two classes of nuisance. There are public nuisances which are offences against the public where there is prejudice to the health of the public generally. And there are private nuisances—acts which are not necessarily harmful in themselves but which result in prejudice to a particular complainant. Behaviour, which is likely to spread disease, was held to be a public nuisance as long ago as 1815 in the case of R. *v.* Vantandillo where a mother had carried along a public highway her child which was suffering from small-pox. In later years the collection of infectious patients in a hospital was deemed a private nuisance in the case of Metropolitan Asylums Board *v.* Hill. Local authorities have, of course, for a long time been authorised to make by-laws to prevent nuisance from rubbish or from the keeping of animals if injurious to health. From this it is not a long step to stagnant ditches which breed mosquitoes. In the recent Paisley case the land-owners pleaded that they had done nothing wrong and that they were not responsible for an act of nature to which they had not contributed. The plea did not serve, nor would it have served in England, where the principle is embedded in the law that a man must so keep what is his that he does not harm his neighbour.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1926 statistics for six districts:—

Name of district and mid-year population	Birth rate	Death rates per 1000 of the population					Death rates per 1000 births		
		All causes	Tuberculosis	Cancer	Resp. diseases with influenza	Heart disease	Diarrhœa under 2 years	Infant mortality	Maternal mort. from childbirth
Wiltshire (298,300)	16·2	11·1	0·60	1·42	1·6	1·8	3·0	50	2·5
Willesden (173,554)	15·5	9·5	0·93	1·37	1·4	1·5	3·7	53	1·9
Sunderland (163,800)	23·1	13·8	1·16	1·18	3·1	1·2	20·4	101	3·1
Grimsby (87,190)	19·8	12·1	1·42	1·35	2·0	1·4	10·2	91	5·8
Stoke Newington (53,080)	16·0	10·7	1·02	1·77	1·8	1·0	7·0	48	4·7
Watford (50,033)	15·2	9·5	1·30	1·28	1·5	1·1	1·3	42	5·2

Wiltshire.

Dr. Claude E. Tangye reports that the towns of Wiltshire have pure and usually adequate water-supplies, but that many of the villages are dependent upon wells which have become hopelessly polluted, and that some of the villages depend upon rain-water only. No new supplies were provided during 1926, but it is hoped that a scheme for Amesbury will be completed in 1927. The recurring appearance of cases of enteric fever at Hindon, coupled with highly polluted wells, has led the Tisbury R.D.C. to formulate a scheme for this parish. The town council of Swindon is promoting a scheme for the extension of their pumping operations at Ogbourne, and at the Ministry inquiry in February, 1927, a protective clause for existing wells within a radius of two miles from Ogbourne was agreed to. A new reservoir is to be constructed by the Trowbridge Water Company to meet the water shortage in Melksham. "Apart from the immediate danger to health involved from contaminated water," says Dr. Tangye, "the milk-producing industry of Wiltshire is likely to suffer in the future if water-supplies to farms remain polluted." The regulations of the new milk order are based on the assumption that a good water-supply is available, and in many Wiltshire farms these requirements cannot be met owing to the dirty and restricted water-supplies. During recent years there has been a great advance in the matter of rivers pollution, but Calne, Malmesbury, and Trowbridge remain to be dealt with. Works at Calne are in progress. At Trowbridge domestic sewage is efficiently treated but unpurified trade refuse is discharged into the Biss. Malmesbury is a source of continuous pollution of the Avon.

Administration of the Milk Act, which became law in September 1925, *has been chiefly confined to dealing* with complaints from outside authorities as to tuberculous milk. During 1926 15 such complaints were received from London County Council, 3 from Salisbury City, and 1 from Woking U.D. As the result 20 cows were identified by the veterinary surgeons as giving tuberculous milk and, with one exception, subsequently slaughtered. Dr. Tangye refers to the difficulty caused by the month's delay in waiting for the result of the biological test and the further month's delay which usually elapses before suspected cows can be proved to be the culprits. Another difficulty is with regard to mixed milk. One of the complaints received referred to the milk of a depôt supplied by 80 farms situated in three counties. These difficulties will, of course, be much reduced when an efficient system of veterinary inspection is in operation in all districts. During the autumn a new joint coordinating subcommittee was formed, including representatives from all the committees dealing with any aspect of the milk question.

An outbreak of food poisoning affecting 40 persons at Downton was thought to be due to cooked ham. Several of those affected were seriously ill but there were no fatal results. The ham was ascertained to be of Danish origin, and a hitherto undescribed bacillus was isolated at the Salisbury laboratory, which on submission to the Lister Institute was stated to be probably of the dysentery type. The county council is the authority for dealing with small-pox, and the new hospital at Ogbourne St. George for the north of the county is now complete. The 317 notifications of diphtheria with 17 deaths is the worst record since 1920. Highworth R.D. with 50 cases, and the town of Devizes with 49 cases, were the most heavily affected districts. Encephalitis lethargica caused 7 deaths among the 20 cases notified and poliomyelitis 4 deaths among the 13 cases notified. The practice of midwifery by unqualified persons has almost ceased. It has been found impossible with the present health visiting staff to extend the supervision of infants up to the school age. The orthopædic scheme centred on the Children's Orthopædic Hospital at Bath is doing good work, but a greatly needed extension is "a satisfactory method of teaching and supervising remedial exercises for postural defects throughout the county."

Willesden

Dr. George F. Buchan reports that year by year four-fifths of the infant deaths in this urban district are due to known causes against which active measures are required. These may be grouped as: (1) congenital malformations, prematurity, &c.; (2) diarrhœa, &c.; and (3) respiratory diseases, including whooping-cough and measles. Of the 143 infant deaths in 1926 62 were caused by the first group, 10 by the second, and 44 by the third. Last year Dr. W. D. Champneys reported on cancer and expressed the opinion that the most important measure would be a cancer clinic for free diagnosis. After the report had been considered by the council the health committee consulted with the local medical advisory committee, and the final outcome was a reference to the health propaganda committee to deal with the question of cancer as a part of health propaganda. There were two cases of small-pox in Willesden during 1926, one of them fatal. The original case, a man of 43, contracted the disease in Paris. He became ill in a London hotel, but the disease was unrecognised. He moved with his wife to a nursing home in Willesden, where his wife became ill with severe hæmorrhagic small-pox and was removed to a small-pox hospital where she died the same evening. The contacts were vaccinated and no further cases occurred in Willesden. Seven cases of typhoid fever were notified, four were removed to the municipal hospital, where two were rediagnosed and one died, this being the only death from typhoid. There were 19 notifications of the infectious diseases of the nervous system with four deaths. Dr. Buchan is much impressed with the value of the work done at the three schools for mothers, and a syllabus of the health talks is included in his report. He complains bitterly, however, of the unsuitability and inadequacy of the premises provided. No progress has been made as regards an open-air school, but a local orthopædic clinic is to be established. The medical staff are taking part in the Board of Education anthropometric inquiry and completed 198 schedules during 1926.

Greater use has been made of Section 111 of the Housing Act of 1925, "but much time is lost in dealing with the disputatious owner." The delay is caused by advertising for tenders, reporting to the committee, and then to the council for acceptance. The owner, in the meantime, obtains information as to progress from the published council agenda and carries out some work. The agreement with the contractor has then to be modified and a new schedule of work and an amended estimate of cost made. The Meat Regulations of 1924 are being observed satisfactorily in Willesden, and one prosecution under the regulations had a salutary effect. At the municipal hospital serum treatment of scarlet fever has given satisfactory results. The percentage of cases with complications has been reduced, and when the serum has been given early the disease has been cut short. There were 306 cases treated without a single death. The Dick test has also been used successfully for the patients in a non-scarlet fever ward after the introduction of a case of scarlet fever. By its means and a subsequent prophylactic dose of scarlet fever antitoxin it is found that complete control over any further occurrence of cases can be maintained. During 1926 the Schick test followed by immunisation has been adopted for the nursing staff in the diphtheria wards. Since its adoption there has been no diphtheria among the nurses, amongst whom previously the incidence of this disease was high. Appendix H is a valuable article on Rheumatism in Childhood by Dr. C. T. Maitland, containing a description of the "rheumatism supervisory centre" of the Paddington Green Children's Hospital. In Appendix I Dr. Alice Gray reports on diphtheria in the Stonebridge area and emphasises the futility of the methods in vogue for the prevention of diphtheria previous to the discovery of the value of the Schick test followed by active immunisation of the susceptible.

Sunderland

Dr. Eustace Thorp (acting medical officer of health for the county borough) says much has been done in the provision of houses for those in regular work, but that little has as yet been planned for that large class, the casual worker, living at present under appalling conditions, who requires his accommodation in the vicinity of the river or his work. There is not much chance also for workers with large young families or for newly married pairs. He thinks the plan of putting old houses into good repair and letting in flats is worth more than a passing thought. Some of these old houses have been well built and can stand alteration and remodelling. The 584 new houses erected during the year included 338 municipal houses and 207 erected with State assistance. Greater efforts are being made by cowkeepers to keep their animals clean. Out of 104 samples of milk examined for tubercle bacilli five gave a positive result. There is a limited number of tradesmen who do not adhere strictly to the rule of the Butchers' Association that, when any abnormality exists or there is any doubt as to the fitness of meat for sale, the advice of the health department should be obtained at once. There are 68 licensed slaughter-houses within the borough. Continued good results in preventing cross infection are reported from the use of the bed isolation ward at the infectious diseases hospital.

Grimsby

Dr. B. C. Stevens reports that the general hospital, with accommodation for 60 patients, serves a wide district, including Cleethorpes and Immingham, and that its sphere of usefulness is curtailed by want of beds. The general level of Grimsby is only one or two feet above ordinary spring tide level and the sewers laid before the erection of the pumping station in 1892 are too flat to be self-cleansing. Three gangs of men with flushing tanks are continuously employed flushing them. There are no street level sewer ventilators and ventilation is achieved by means of shafts erected against buildings and since 1910 by vent columns. For four-fifths of the town pumping of the sewage has to be employed, the periods of pumping and of discharging by gravitation being about equal. The remaining fifth of the town is drained by gravitation, the sewage being held up for about half the time by a penstock. Thanks to the additional pumping capacity there is now no flooding even when a heavy rainfall coincides with spring tides. The town is now practically free of box privies. The hospital pavilion, with 24 beds for advanced cases of tuberculosis, was opened in July, since which it has been fully occupied The *two notified cases of puerperal fever both* terminated fatally Antiscarlet-fever serum was used for septic cases and helped to reduce the temperature, but in one case did not prevent the formation of two abscesses and otitis media Of the 94 cases of diphtheria admitted to hospital from Grimsby all recovered, and this good result is claimed to be due to the early use of antitoxin and prompt bacteriological reports from the municipal laboratory The V D scheme has been improved by the substitution of eight sessions in the week for five New cases of syphilis show a reduction of 35 per cent and all the pregnant syphilitic women attending the clinic have given birth to full-term healthy babies

Stoke Newington

Prof Henry Kenwood, in the last of his long series of annual reports for this metropolitan borough, draws attention to the large number of deaths of Stoke Newington residents which occur in public institutions outside the borough During 1926 266 of the 568 deaths occurred in such institutions During the *first two years of the borough's existence (1901–02) the* number of these deaths was only one-half of the 1926 figure Dr Kenwood points out that nearly half the infant mortality occurs during the first month and that, while during the past 20 years the infant mortality-rate has fallen by 50 per cent, the neonatal rate has remained stationary Dr Kenwood has *endeavoured to arrange with the London hospitals for* a notice to be sent to the borough maternity and child welfare department when children requiring after-care are discharged from hospital He has supplied notification forms to the various hospitals with stamped and addressed envelopes, but so far has not received the full information desired He thinks the general adoption in London of such a system would be of great benefit to the children and would also be a relief to the hospital almoners During the year arrangements have been made with the British Dental Hospital to equip and maintain a surgery on the council's premises and to provide, direct, and supervise a dentist at an inclusive charge of £120 yearly This scheme will provide dental treatment in connexion with the maternity and child welfare work—a scheme similar to that adopted in Battersea, Hampstead, Holborn, Shoreditch, and Stepney

Watford

Dr William J Cox states that the housing question in the borough still remains one of great difficulty and that there are about 1500 families waiting for municipal houses, in spite of the fact that 953 municipal houses have been erected since 1920 and that 172 are in hand In addition 114 non-parlour houses have been erected on the Wiggenhall Estate to rehouse the tenants of houses closed In 1921 the late Dr A King, M O H, scheduled six areas including 249 insanitary houses, of which 138 have been dealt with up to now The Watford Joint Isolation Hospital had an unusual experience during 1926 in having to admit 20 blind infants and most of the staff from Sunshine House, Chorley Wood An epidemic affected practically everyone in this institution and was subsequently decided to be German measles All the cases were mild Out of 173 samples of milk examined 7 were found to contain tubercle bacilli and 20 blood or pus cells Watford is an important centre for the slaughter of animals, and the " Kosher " method is practised at one large slaughter-house. The *consultations at the* antenatal centre are well attended; the number of expectant mothers for 1926 was 276, while the total births were 775 The dental work is also increasing The orthopædic centre under Mr S L Higgs dealt with 62 Watford children sent from the infant welfare centre suffering from various deformities This institution is an out-centre for an orthopædic hospital and serves the neighbouring district Dr Cox, as assistant school medical officer for Herts, is responsible for the medical inspection of half the Watford schools, and states that there is very little difficulty in obtaining treatment for the ailments of the children when the need has been pointed out to the parents Reinspection by the dentist shows an increasing percentage of children with sound dentures year by year.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 11TH, 1927

Notifications—The following cases of infectious disease were notified during the week —Small-pox, 243 (last week 254), scarlet fever, 1428, diphtheria, 668, enteric fever, 80, pneumonia, 915, puerperal fever, 43, puerperal pyrexia, 90, cerebro spinal fever, 14, acute poliomyelitis, 6, encephalitis lethargica, 32, dysentery, 4, ophthalmia neonatorum, 113

Cases of small-pox were notified from the counties of Derby 2, Durham 125, Kent 1 (Gravesend), Lancaster 13, Northumberland 15, Nottingham 2 (Mansfield and Mansfield Woodhouse), Stafford 4, Warwick 1 (Coventry), Yorks North Riding 1 (Eston), Yorks West Riding 38, City of York 1, *Glamorgan 7, Monmouth 33 None was returned from* London, Middlesex, or Surrey

Deaths—In the aggregate of great towns, including London, there were no deaths from small-pox, 4 (2) from enteric fever 43 (1) from measles, 6 (1) from scarlet fever, 31 (9) from whooping-cough, 11 (2) from diphtheria, 47 (10) from diarrhœa and enteritis under two years, and 33 (4) from influenza The figures in parentheses are those for London itself

The Services.

ROYAL ARMY MEDICAL CORPS

THE undermentioned Capts to be Majs D Cran (Prov), L A J Graham, and J C Denvir

Capt L C Goument retires, receiving a gratuity.

R S de C Bennett to be temp Lt

ARMY DENTAL CORPS

Capt J V M Byrne to be Maj

TERRITORIAL ARMY

Col Sir George T Beatson vacates the appt of Hon Col R A M C Units, 52nd (Lowland) Div, on completion of tenure

Col G H Edington (retd) to be Hon Col R A M C Units, 52 (Lowland) Div

Lt O G Misquith, late R A M C, T A, to be Lt

W R Ward, late Surg Sub-Lt, R N V R, to be Lt

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt R M Savege, from the Active List, to be Capt

District, vice Maj B Johnson. Maj R M Davies to be officiating D A D M S (Mobilisation), Rawalpindi District. Maj R Davidson to be Depy Asst. Director of Hygiene, Baluchistan District, vice Maj A. S Cane Lt -Col F E Wilson has been appointed Civil Surgeon, Quetta Maj R R M Porter, professor of surgery, Prince of Wales Medical College, Patna, has been appointed to officiate as Principal Dr G B Chikerur has been appointed Honorary Physician of the Civil Hospital, Jalgaon Dr Ram Taran Sen, civil assistant surgeon, has been appointed as Supernumerary at Shillong Dr Ivy Kees has been appointed Medical Officer in Charge Dufferin Hospital, Allahabad, vice Dr E S Walker, on leave Dr Narayan Das Banarji, medical officer in immediate charge, Sadr Dispensary, Bahraich, to officiate as Civil Surgeon, Bahraich Dr Sri Ram, medical officer in immediate charge, Sadr Dispensary, Fatehpur, to officiate as Civil Surgeon, Fatehpur Dr J C Roy Chaudhry, officiating civil surgeon, Hamipur, has been appointed Medical Officer in immediate charge, Sadr Dispensary, Rae Bareli Maj -Gen A. Hooton has been appointed a Member of the Council of State, vice Maj -Gen Symons

RETIREMENT OF I M S OFFICERS HOLDING ADMINISTRATIVE APPOINTMENTS

The following change as to the age at which officers in the Indian Medical Service holding administrative appointments will be placed on the Retired List has been made General officers will be placed on the retired list at the age of 60 instead of as heretofore at the age of 57, and the provision whereby a general officer holding an administrative appointment may be continued in employment for not more than one year in any special case will be cancelled

I M S ANNUAL DINNER

The annual dinner of the Indian Medical Service held at the Trocadero, London, on June 15th, was the third largest gathering since the Dinner Fund was inaugurated in 1897 by Sir Peter Freyer His memory is now honoured in the handsome cup placed in front of the chairman of the evening, who was on this occasion Major-General R W S Lyons Sir Dawson Williams and Dr E C Morland were present as guests The members of the Service who attended were as follows —

Major Generals Sir R H Charles, G C V O , K C S I , B H Deare C I E G F A. Harris, C S I , Sir P Hehir, K C.I E , C B , C M.G , H Hendley, C S I W H Ogilvie, C B , C.M G (D M.S), J B Smith, C B , C I E , T H Symons, C S I , O B E (D G)

Air Vice Marshal D Munro, C B , C I E

Colonels H Ainsworth , Sir H E Banatvale, C S I , J K Close , J Crimmin, V C , C B C I E , C M Goodbody, C I E., D S O , J A. Hamilton, C M G A W M Harvey , A J Macnab C B , C M G , R A. Needham, C I E , D S O , J J Pratt , H Austen Smith C I E , R. G Turner, C M G , D S O F Wall, C M G , C N Wimerbley, C M.G

Lieut Colonels J Anderson C I E W M Anderson, C.I.E. , F A Barker, O B E G T Birdwood J T Calvert, C I E., R Markham Carter, C B A W Cook-Young , D G Crawford J M Crawford, O B E , H R Dutton , R H Elliot , J Entrican, C I E , G H Frost , J Fuller Good H Greany E V Hugo, C M.G , J B Dalzell Hunter, O B E , J G Jordan , H C Keates ,H Kirkpatrick J C G Kunhardt , Clayton Lane W B Lane, C I E , C B E , W T McCowen G E Malcolmson W A Mearns , F O N Mell C I.E A. "Audi alteram partem"

ETHER CONVULSIONS

To the Editor of The Lancet

Sir,—I am interested in Dr S R Wilson s article on this subject in The Lancet of May 28th (p 1117), but I do not think that the impurities of the ether were responsible for the convulsions and deaths mentioned The cause of death is stated in the article, but has evidently been overlooked: "The lungs were congested and a small amount of frothy fluid exuded on pressure" This corresponds to the findings of Charles W Hooper and myself in a study of the experimental value of preliminary medication with all of the various anæsthetics This study lasted over a year, and over 500 animals were used

Experimental Procedure—Healthy, non-pregnant albino rats, weighing approximately 150 g , were used; they were obtained from one source and were kept on a constant well-balanced diet for at least two weeks before the tests They were fasted for from 16 to 20 hours immediately before the injection of the drug, when they were weighed and the dosage administered per kilo body-weight. Water was supplied during the fast period Two animals were given magnesium sulphate, morphine, and novocaine dissolved in distilled water and injected into the saphenous vein Two animals used as controls were given no medication whatever All four animals were then placed in a glass receptacle and received the same amount of the anæsthetic. Regardless of the anæsthetic used, whether ether, nitrous oxide-oxygen, or one of the hydrocarbon gases (acetylene, ethylene, or propylene), the animals not receiving preliminary medication were found to have pathological lesions in the lungs at necropsy This was especially true and more marked with ether than with the other anæsthetics The lungs were usually distended, congested, œdematous, and contained petechiæ With ether, atalectasis involving a portion of one lobe, and often massive atalectasis involving one or more of the lobes The lungs of the animals that received preliminary medication were normal

In Dr Wilson's article no mention is made of any of the patients receiving preliminary medication, but the "convulsions" referred to could easily have been induced by the difficulty in getting sufficient oxygen to the brain through the lung in order to sustain life Under the microscope the pathological lesions referred to in the above experiments showed the alveolar spaces filled with œdematous fluid. There was a perivascular œdema and the bronchi contained coagulated œdematous fluid This work has not been published yet, although it was reported at the last meeting of the American Association of Thoracic Surgeons in May The margin of safety is considerably increased by preliminary medication

The cause of pathological lesions occurring in the lungs of these experimental animals, and also clinically, we do not know Possibly it might be explained by the hypernœa followed by apnœa that usually occurs, especially with ether, when no preliminary medication is given Trusting that this communication may throw some light on the subject,

I am, Sir, yours faithfully,

New York, June 10th, 1927 James T Gwathmey

THE LOCAL ADMINISTRATION OF MENTAL DEFICIENCY

To the Editor of The Lancet

Sir —Your article and Dr Tredgold's letter in The Lancet of June 18th raise a very important question as to the position of specialists in the public health service I think we may at once discount Dr Tredgold's assumption that mental deficiency is to be treated as in a different category from "venereal disease. tuberculosis infectious diseases inspection and treatment of school-children" The specialists in some at least of these branches of medicine might and do claim like Dr Tredgold that with 24 beds for advanced cases of tuberculosis, was opened in July, since which it has been fully occupied The two notified cases of puerperal fever both terminated fatally Antiscarlet-fever serum was used for septic cases and helped to reduce the temperature, but in one case did not prevent the formation of two abscesses and otitis media Of the 94 cases of diphtheria admitted to hospital from Grimsby all recovered, and this good result is claimed to be due to the early use of antitoxin and prompt bacteriological reports from the municipal laboratory The V D scheme has been improved by the substitution of eight sessions in the week for five New cases of syphilis show a reduction of 35 per cent and all the pregnant syphilitic women attending the clinic have given birth to full-term healthy babies

Stoke Newington

Prof Henry Kenwood, in the last of his long series of annual reports for this metropolitan borough, draws attention to the large number of deaths of Stoke Newington residents which occur in public institutions outside the borough During 1926 266 of the 568 deaths occurred in such institutions During the first two years of the borough's existence (1901–02) the number of these deaths was only one-half of the 1926 figure Dr Kenwood points out that nearly half the infant mortality occurs during the first month and that, while during the past 20 years the infant mortality-rate has fallen by 50 per cent, the neonatal rate has remained stationary Dr Kenwood has endeavoured to arrange with the London hospitals for a notice to be sent to the borough maternity and child welfare department when children requiring after-care are discharged from hospital He has supplied notification forms to the various hospitals with stamped and addressed envelopes, but so far has not received the full information desired He thinks the general adoption in London of such a system would be of great benefit to the children and would also be a relief to the hospital almoners During the year arrangements have been made with the British Dental Hospital to equip and maintain a surgery on the council's premises and to provide, direct, and supervise a dentist at an inclusive charge of £120 yearly This scheme will provide dental treatment in connexion with the maternity and child welfare work—a scheme similar to that adopted in Battersea, Hampstead, Holborn, Shoreditch, and Stepney.

Watford

Dr William J Cox states that the housing question in the borough still remains one of great difficulty and that there are about 1500 families waiting for municipal houses, in spite of the fact that 953 municipal houses have been erected since 1920 and that 172 are in hand In addition 114 non-parlour houses have been erected on the Wiggenhall Estate to rehouse the tenants of houses closed In 1921 the late Dr A King, M O H, scheduled six areas including 249 insanitary houses, of which 138 have been dealt with up to now The Watford Joint Isolation Hospital had an unusual experience during 1926 in having to admit 20 blind infants and most of the staff from Sunshine House, Chorley Wood. An epidemic affected practically everyone in this institution and was subsequently decided to be German measles All the cases were mild. Out of 173 samples of milk examined 7 were found to contain tubercle bacilli and 20 blood or pus cells Watford is an important centre for the slaughter of animals, and the " Kosher " method is practised at one large slaughter-house The consultations at the antenatal centre are well attended; the number of expectant mothers for 1926 was 276, while the total births were 775 The dental work is also increasing The orthopædic centre under Mr S L Higgs dealt with 62 Watford children sent from the infant welfare centre suffering from various deformities This institution is an out-centre for an orthopædic hospital and serves the neighbouring district Dr Cox, as assistant school medical officer for Herts, is responsible for the medical inspection of half the Watford schools, and states that there is very little difficulty in obtaining treatment for the ailments of the children when the need has been pointed out to the parents Reinspection by the dentist shows an increasing percentage of children with sound dentures year by year

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 11TH, 1927

Notifications—The following cases of infectious disease were notified during the week —Small-pox, 243 (last week 254); scarlet fever, 1428, diphtheria, 668, enteric fever, 80, pneumonia, 915, puerperal fever, 43, puerperal pyrexia, 90, cerebro spinal fever, 14, acute poliomyelitis, 6, encephalitis lethargica, 32, dysentery, 4, ophthalmia neonatorum 113

Cases of small-pox were notified from the counties of Derby 2, Durham 125, Kent 1 (Gravesend), Lancaster 13, Northumberland 15, Nottingham 2 (Mansfield and Mansfield Woodhouse), Stafford 4, Warwick 1 (Coventry), Yorks North Riding 1 (Eston), Yorks West Riding 38, City of York 1, Glamorgan 7, Monmouth 33 None was returned from London, Middlesex, or Surrey

Deaths—In the aggregate of great towns, including London, there were no deaths from small-pox, 4 (2) from enteric fever, 43 (1) from measles, 6 (1) from scarlet fever, 31 (9) from whooping-cough, 11 (2) from diphtheria, 47 (10) from diarrhœa and enteritis under two years, and 33 (4) from influenza The figures in parentheses are those for London itself

The Services.

ROYAL ARMY MEDICAL CORPS

THE undermentioned Capts to be Majs D Cran (Prov), L A J Graham, and J C Denvir

Capt L C Goument retires, receiving a gratuity

R S de C Bennett to be temp Lt

ARMY DENTAL CORPS

Capt J V M Byrne to be Maj

TERRITORIAL ARMY

Col Sir George T Beatson vacates the appt of Hon. Col R A.M.C Units, 52nd (Lowland) Div, on completion of tenure

Col G H Edington (retd) to be Hon Col R A M C Units, 52 (Lowland) Div

Lt O G Misquith, late R A M C, T A, to be Lt

W R Ward, late Surg Sub-Lt, R N V R, to be Lt

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt R M Savege, from the Active List, to be Capt

ROYAL AIR FORCE

E P Carroll and G W McAleer are granted short service commissions in the rank of Flying Officer for three years on the active list

INDIAN MEDICAL SERVICES

The King has approved of the retirement of Lt-Cols E O Thurston and T G N Stokes

Capt J D L Yule to be Maj

Lt J E Gray to be Capt. (Prov)

Lt.-Col W M H Spiller to be officiating A.D M S, C P District, vice Col E P Sewell, on leave Capt C S V Ramanan has been appointed Specialist in Ophthalmology, Madras District (temporarily), vice Maj E F W Grellier Captain C S Allagappan has been appointed Specialist in Surgery, Secunderabad, vice Capt. G A Whitfield Maj E F W Grellier has been appointed Specialist in Ophthalmology, Lahore District, vice Maj R. M Dickson Maj G D R Carr has been appointed Surgical Specialist, Lahore District, Lahore (temporarily), vice Maj R. V. Vint Maj C H H. Dr G B Chikerur has been appointed Honorary Physician of the Civil Hospital, Jalgaon Dr. Ram Taran Sen, civil assistant surgeon, has been appointed as Supernumerary at Shillong Dr Ivy Kees has been appointed Medical Officer in Charge Dufferin Hospital Allahabad, vice Dr E S Walker, on leave Dr Narayan Das Banarji, medical officer in immediate charge, Sadr Dispensary Bahraich to officiate as Civil Surgeon Bahraich Dr Sri Ram medical officer in immediate charge, Sadr Dispensary, Fatehpur, to officiate as Civil Surgeon, Fatehpur Dr J C Roy Chaudhry, officiating civil surgeon, Hamipur, has been appointed Medical Officer in immediate charge, Sadr Dispensary, Rae Bareli Maj-Gen. A. Hooton has been appointed a Member of the Council of State, vice Maj-Gen Symons

RETIREMENT OF I M S OFFICERS HOLDING ADMINISTRATIVE APPOINTMENTS

The following change as to the age at which officers in the Indian Medical Service holding administrative appointments will be placed on the Retired List has been made General officers will be placed on the retired list at the age of 60 instead of as heretofore at the age of 57, and the provision whereby a general officer holding an administrative appointment may be continued in employment for not more than one year in any special case will be cancelled

I M S · ANNUAL DINNER

The annual dinner of the Indian Medical Service held at the Trocadero, London, on June 15th, was the third largest gathering since the Dinner Fund was inaugurated in 1897 by Sir Peter Freyer His memory is now honoured in the handsome cup placed in front of the chairman of the evening who was on this occasion Major-General R. W S Lyons Sir Dawson Williams and Dr E C Morland were present as guests The members of the Service who attended were as follows —

Major-Generals. Sir R H Charles, G C V O, K.C S I, B H Deare C I E G F A. Harris, C S I, Sir P Hehir, K.C.I E. C B, C M.G H Hendley, C S I W. H Ogilvie C B, C.M.G (D M.S), J B Smith, C B, C I E., T H Symons, C S I, O B E. (D G)

Air Vice-Marshal D Munro, C B, C I.E.

Colonels H Ainsworth Sir H E. Banatvale, C S I, J K Close, J Crimmin, V C, C B C I.E., C M. Goodbody, C.I E., D S O, J A. Hamilton, C M.G A. W M Harvey A. J Macnab, C B, C M.G, R A. Needham, C I E, D S O, J J Pratt H Austen Smith C.I E., R G Turner, C M.G, D S O, F Wall, C M.G C N Wimerbley, C M.G

"Audi alteram partem"

ETHER CONVULSIONS

To the Editor of THE LANCET.

SIR,—I am interested in Dr S R Wilson s article on this subject in THE LANCET of May 28th (p 1117), but I do not think that the impurities of the ether were responsible for the convulsions and deaths mentioned The cause of death is stated in the article, but has evidently been overlooked "The lungs were congested and a small amount of frothy fluid exuded on pressure" This corresponds to the findings of Charles W. Hooper and myself in a study of the experimental value of preliminary medication with all of the various anæsthetics This study lasted over a year, and over 500 animals were used

Experimental Procedure —Healthy, non-pregnant albino rats, weighing approximately 150 g, were used; they were obtained from one source and were kept on a constant well-balanced diet for at least two weeks before the tests They were fasted for from 16 to 20 hours immediately before the injection of the drug, when they were weighed and the dosage administered per kilo body-weight. Water was supplied during the fast period Two animals were given magnesium sulphate morphine and novocaine dissolved in distilled water and injected into the saphenous vein Two animals used as controls were given no medication whatever All four animals were then placed in a glass receptacle and received the same amount of the anæsthetic Regardless of the anæsthetic used, whether ether, nitrous oxide-oxygen, or one of the hydrocarbon gases (acetylene, ethylene, or propylene), the animals not receiving preliminary medication were found to have pathological lesions in the lungs at necropsy This was especially true and more marked with ether than with the other anæsthetics The lungs were usually distended, congested, œdematous, and contained petechiæ. With ether, atalectasis involving a portion of one lobe and often massive atalectasis involving one or more of the lobes The lungs of the animals that received preliminary medication were normal

In Dr Wilson s article no mention is made of any of the patients receiving preliminary medication but the "convulsions" referred to could easily have been induced by the difficulty in getting sufficient oxygen to the brain through the lung in order to sustain life Under the microscope the pathological lesions referred to in the above experiments showed the alveolar spaces filled with œdematous fluid There was a perivascular œdema and the bronchi contained coagulated œdematous fluid This work has not been published yet, although it was reported at the last meeting of the American Association of Thoracic Surgeons in May The margin of safety is considerably increased by preliminary medication

The cause of pathological lesions occurring in the lungs of these experimental animals, and also clinically, we do not know. Possibly it might be explained by the hypernœa followed by apnœa that usually occurs, especially with ether. when no preliminary medication is given Trusting that this communication may throw some light on the subject

I am Sir, yours faithfully

New York, June 10th, 1927 JAMES T. GWATHMEY

THE LOCAL ADMINISTRATION OF MENTAL DEFICIENCY

To the Editor of THE LANCET

SIR —Your article and Dr Tredgold s letter in THE LANCET of June 18th raise a very important question as to the position of specialists in the public health service I think we may at once discount Dr Tredgold s assumption that mental deficiency is to be treated as in a different category from "venereal disease tuberculosis infectious diseases, inspection and treatment of school-children" The specialists in some at least of these branches of medicine might and do claim like Dr Tredgold that their specialism is one of which adequate knowledge for administration cannot be acquired by any but the specialist Much might be said on the subject of extreme specialism from the purely medical standpoint, but I intend to confine myself to the administrative question

Our problem is to find the most efficient organisation through which all this specialised knowledge may be placed at the service of the public. Broadly, there are three ways in which it may be—done either by creating a series of specialist departments with a specialist administrative officer according to the method which Dr Tredgold advocates for mental deficiency, or to have one principal medical officer with a staff of assistants, which is in line with the traditions of the public health service in this country, or to work through a department the principal officer of which is a trained lay administrator making use of technical or specialist officers for appropriate purposes The last method has not been adopted in this country and is contrary to the existing law, but it should be noted that keen and enthusiastic public representatives have advocated it because of the alleged lack of business capacity among medical men in administrative positions I have mentioned it, not because I think the proposal worthy of serious consideration by the medical profession, but as illustrating the recognised importance of good business management While successful medical administration must depend on an understanding of the medical questions involved, administrative ability does not necessarily accompany highly specialised knowledge Like most other things it is usually acquired by apprenticeship and experience, and it is at least doubtful if it is an economic proposition to demand that every specialist in the branches of preventive medicine should qualify himself to be an expert administrator In any case, it is a fact that many of the most highly qualified specialists are peculiarly weak on the business side On the other hand, the medical officers of health of the present day are to an increasing extent men who have clinical experience of the sections of their department including mental deficiency, and are well able to consider the several problems of these sections from the medical point of view, while at the same time the associated administrative, business, and financial questions receive the attention which the public and their representatives demand. For these reasons there is much to be said for the second type of organisation in preference to the first

There is, however, the further great question of coordination This emphatically cannot be attained by the simple procedure of "placing administrative control in the hands of one and the same council" Local government is increasing in scope and complexity and the amount of coordination which can be deliberately and constantly exercised by a council is infinitesimal In practice, committees are formed for various purposes, and those which have strong chairmen are apt to develop their services at the expense of the others, for there is a limited amount of money available for all local government purposes Sectional and ill-balanced development of the medical services occurs much more frequently where these committees have not one but several independent officers of different degrees of acceptability to the lay mind In these circumstances such control and coordination as there is rests in the hands of the finance committee, and, if there is not one strong and important medical officer to whom large questions may be referred, the power inevitably passes into the hands of the chief financial officer of the council Is this the sort of coördination which the medical profession would desire?

So far as mental deficiency is a medical question at all, there is, therefore, much to be said for its remaining within the department of the medical officer of health, especially in view of the fact that a large proportion of the defectives—those of school age—already come under his purview if he is school medical officer The status of the officer or officers who do the routine work is thereby, of course, diminished, but it is an open question as to whether their prospects are not enhanced rather than limited by their association with the general health service, although their emoluments for the time being may be less The combined efforts of medical officers of health have already been much more successful in raising the salaries of their assistants than their own, and it must be our constant endeavour to see that specialist knowledge is adequately rewarded Further, no medical officer of health who appreciates the importance of the clinical services he controls will make any secret of the fact that the responsible sectional officers know more about the details of their cases than he does or that he depends upon them for opening up the problems which require administrative solution

The point is that one important medical officer should have the duty of guiding the council in the distribution of a strictly limited supply of public money among the various medical and allied services What official can serve that function but the medical officer of health? The advantages of this arrangement have long ago been recognised by other Government departments, and it is not likely that much more will be heard of the Board of Control's attempt to break away I am, Sir, yours faithfully,

RALPH M F PICKEN

City Hall, Cardiff, June 20th, 1927

To the Editor of THE LANCET

SIR,—In commenting on Dr Tredgold's interesting letter I shall perhaps be the less suspect by him if I make it clear that I happen to have had no part in the preparation of the memorandum from the Society of Medical Officers of Health to which he takes such grave objection The kernel of the case which Dr Tredgold is maintaining is that, to remedy the alleged failure of local authorities to put the Mental Deficiency Act into effect, mental deficiency should in each area be under the administrative control of a mental expert reporting direct to the appropriate committee of his council, and independent of the medical officer of health, "meeting him on equal terms" as a colleague.

Few will disagree with the desire for the appointment of consultants for the diagnosis of the exceptional case and for advice on the proper measures of treatment and care, especially if he is adequately seized of the great importance of the psychological study of the individual social and domestic difficulties which may have been the decisive factors in pushing the patient over the line of mental dullness into mental deficiency But the separation from general public health which, whatever Dr Tredgold may think, does in practice occur when public health work is removed from the sphere of the *medical officer of health*, would be the gravest of steps for the mentally defective themselves Such a separation would cleave a gulf between the feeble-minded on the one hand, under the control of the new "medical officer for mental health," and on the other, the dull and backward child, as well as the infant and young child, who would continue to be under the supervision of the medical officer of health Dr Tredgold and the Board of Control cannot be aware of the loss of coördination and efficiency and the waste of effort to be found where the school medical service is kept separate from the public health department, even though it fulfils Dr Tredgold's requirements of being under a committee of the same Council How much more would this apply to mental deficiency, so much less familiar to the general public? Only by the closest linking up with the general activities of public health can this difficulty be overcome In mental disease, far more than in physical disease, there is amongst the general public a fear of the expert, and the direction of the administrative machinery of mental deficiency by such an expert might well engender a timidity in the public not conducive to successful working.

But this represents the superficial and not the fundamental objection, and it is the fundamental objection which I must now attempt to set out If the public administration of mental deficiency were in the hands of the expert—in particular of the large number of experts of varying experience and bias who would enter into the national scheme—there would be a great risk of diagnosis of too many rather than too few cases of mental defect It is infinitely better to have even considerable under-diagnosis (though not failure to examine all suspects) than the most remote risk of the premature labelling of the borderline case The non-expert is less likely to err in this direction than the expert For many patients on the borderline between mental backwardness and deficiency the attachment of the label of mental deficiency implies the loss of all incentive towards effort by the patient and his relatives, and its replacement by a hopeless acceptance of inferiority In such cases investigation of adverse environmental factors peculiar to the patient might have given him and his household courage for renewed effort, a fresh view of his difficulties and renewed hope to overcome them The Board of Control find that local authorities are at present failing in their ascertainment of cases This may in part indicate neglect, which is remediable It no doubt implies also that largely this borderline group of cases is not being so freely labelled as feeble-minded as might be the case under the direction of the expert That fact lies at the root of the objection to the rule of the expert —I am, Sir, yours faithfully,

H P NEWSHOLME

Public Health Department, Town Hall, Croydon,
June 21st, 1927

PETECHIASIS

To the Editor of THE LANCET

SIR,—Reading in your last week's issue Dr Moreland McCrea's very able article on petechiasis, I was specially interested in his suggestion that excessive loss at the periods or between them may on occasion be due to a generalised toxin acting on the vessels of the endometrium The fact is that the changes that occur in the endometrium during normal menstruation are themselves akin to petechiasis, that is to say, that a transudation of red blood corpuscles through the still intact walls of the endometrial capillaries precedes the actual breakdown of the capillaries The endometrium is in fact being acted on by some substance conveyed to it by the blood stream The exact nature of the substance is unknown, as also its seat of formation, but as far as its effect on the endometrium is concerned, it is to all intents and purposes a " toxin "

I am, Sir, yours faithfully,

VICTOR BONNEY

Devonshire-place, W , June 18th, 1927

FAT AND TUBERCLE

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan 8th Dr W B Vaile published an investigation into the incidence of pulmonary tuberculosis in families exposed to infection, with the object of finding some common factor which governed the principle of selection of victims of the disease Having investigated the home conditions of more than 40 families in which tuberculosis infection had occurred, he found that it was most frequently those members who did not eat fat, and had avoided it as far as possible all their lives, who fell victims to the disease He came to the conclusion that, although the fat-eater has no absolute immunity, and the " fat-shy " is not doomed to the disease, there is a tendency for the " fat-shy " to be more readily infected than the fat-eater

I have investigated the likes and dislikes in regard to fat of 228 patients at present under treatment in the King George V Sanatorium Adopting the same procedure as Dr Vaile, and making allowance for the fact that even " fat-shy " people will eat over-cooked fat, such as fried bacon fat, I find that the numbers in the two categories are .—

Fat-eaters .	126	Fat-shy .	102

These results are of course not comparable with those obtained by Dr Vaile, for he examined the members of families living under identical conditions, and included non-infected as well as infected in tabulating his results In my investigation only infected male adults are available for inquiry, and these patients have come from parts of London differing widely in regard to environment and type of home Further, to be able to correlate the incidence of tuberculosis with a disability to eat fats, it is necessary to know what is the average proportion of fat-eaters to non-fat-eaters in the total population, and particularly in the male population On this point no statistics are at present available, but it is reasonable to presume that fat-eaters preponderate greatly over non-fat-eaters The lowering of this proportion to almost one to one amongst persons infected with pulmonary tuberculosis supports the contention put forward by Dr Vaile

My observations will appear in the forthcoming annual report of the Metropolitan Asylums Board I am quoting the figures now in the hope that others may test Dr Vaile's interesting hypothesis

I am Sir, yours faithfully,

DOUGLAS PORTER,

Senior Assistant Medical Officer, King George V
June 20th, 1927 Sanatorium, Godalming

CHICKEN-POX AND HERPES ZOSTER

To the Editor of THE LANCET.

SIR,—In view of the notes on this subject which have appeared in your columns from time to time, the following case will be of some interest A youth of 19 years was reported to the Health Department as suffering from chicken-pox In view of his age, it seemed advisable for me to see him, when I found a definite chicken-pox rash and herpes zoster of the intercostal type, which had appeared at the same time

I am, Sir, yours faithfully,

E THORP,

Assistant Medical Officer of Health,
June 17th, 1927 Sunderland.

WILLIAM MACKENZIE MEMORIAL —With a view to the encouragement of original work in ophthalmology a William Mackenzie Memorial Fund has been established in Glasgow. More than a century has passed since Mackenzie entered upon the practice of ophthalmology and founded the Glasgow Eye Infirmary, and it is nearly 100 years since the publication of his " Treatise on the Diseases of the Eye " A small committee will be elected annually, consisting of ophthalmic surgeons in Glasgow, and this committee will have a wide discretion as to the way in which the income of the fund is to be expended A medal will be awarded from time to time to the author of original work of outstanding merit in ophthalmology, and, so far as the income permits, grants may be given in aid of research or for other kindred purposes Contributions towards the fund are being received by Dr A J Ballantyne, 11, Sandyford-place, Glasgow, C 3.

DONATIONS AND BEQUESTS —Mr Lewis Spokes Richards, Edgbaston, Birmingham, left to the Royal Orphanage, Wolverhampton, a sum sufficient to endow a cot for boys , £1000 each to the Children's Hospital, Birmingham, the Birmingham Cripples' Union and Royal Orthopædic and Spinal Hospital, the Birmingham Bluecoat School and Dr Barnardo's Homes , and £500 each to the Birmingham Eye Hospital, the Birmingham Ear and Throat Hospital, the Birmingham Blind Asylum, the Birmingham Deaf and Dumb Asylum, and the Aston Manor Nursing Institution —Mr William Beldam, Littlehampton, left £1000 to the Littlehampton and District Hospital ; £300 to the Crawley Cottage Hospital , £100 each to the Girl Guides, Littlehampton, the Boy Scouts, Littlehampton and Arundel Branch , St. John's Ambulance Brigade , and the Littlehampton and District Nursing Association —Mr Whiteley Varley, of Hebden Bridge, left £500 to the Halifax Royal Infirmary and £500 to any public nursing home or hospital at Hebden Bridge,

Obituary.

ALEXANDER HUGH FREELAND BARBOUR, M D , LL D , F R C P EDIN.

THE sudden and unexpected death of Dr. Freeland Barbour on June 11th is felt with deep regret in Edinburgh, not only by the medical profession but throughout the city, for apart from his work as a gynæcologist, Dr Barbour was a pillar of the United Free Church, and is widely remembered as a man who was always ready to give where help was needed

Born in 1856, he was the youngest son of the late G F Barbour, of Bonskeid and Gryffe, and was educated in the University of Edinburgh, where he graduated as M A in 1875 and B Sc in 1877 Two years later he took a medical degree, and went over to the continent to continue his studies at Berlin, Paris, Vienna, and other centres Returning to Edinburgh he became a Member of the Royal College of Physicians in that city, and two years later a Fellow From this time he was closely associated with the College, and in 1914 was elected its President In 1883 he was awarded a gold medal for his M D thesis on Spinal Deformity in Relation to Obstetrics, a paper which was the result of painstaking original research, and which proved to be the first of a series which have considerably influenced gynæcological practice Henceforward he devoted himself to gynæcological work, and became assistant to his brother-in-law, the late Prof A R Simpson, before being appointed physician to the Simpson Memorial Royal Maternity Hospital and gynæcologist to the Royal Infirmary of Edinburgh, in both of which institutions he served a full term of office His teaching was always an important element in his success, for many years he was a successful teacher in the extra-mural school, and on the institution of a lectureship of gynæcology in the University it was natural and fitting that he should be appointed to this post, in which he maintained and enhanced the traditions of the obstetrical school founded by Sir J Y Simpson His knowledge of examinational standards led to his appointment as inspector of examinations in midwifery for the General Medical Council To those that studied under him his clear and lucid descriptions will ever be remembered, and his interest in his classes was personal as well as instructional He was one of the few who continued to live in Charlotte-square—long considered the home of medicine in Edinburgh—and here he entertained students of all classes and nationalities In character he was quiet, kindly, and unassuming, and his religious belief had always its practical application

DR FREELAND BARBOUR

Photograph by A Swan Watson Edinburgh

It is by his publications that Dr Barbour's work is best known to the medical profession at large His "Manual of Gynæcology," written in collaboration with the late Dr Berry Hart, was for a quarter of a century a leading British text-book, and ran rapidly through many editions, being translated into French, Italian, Spanish and finally Chinese His latest work, "Gynæcological Diagnosis and Pathology," was written with Prof B P Watson, formerly one of his pupils, and is already well known His "Atlas of the Sectional Anatomy of Labour" is another classical work which testifies to a detailed knowledge of this intricate subject Other contributions to the literature will be found in the Transactions of the Obstetrical Society of Edinburgh

Dr Barbour's eminence as a gynæcologist was recognised by the Universities of Edinburgh and Toronto, which conferred on him the degree of Doctor of Laws, and he was made a Corresponding Fellow of the Royal Academy of Medicine of Turin and the Obstetrical Society of Leipzig In 1889 he married Margaret Nelson, elder daughter of the Hon George Brown of Toronto She survives him, with two sons and three daughters

HENRY CECIL EARL, M D. DUB., F R C P IREL

THERE is much regret among members of the medical profession in the Irish Free State at the death of Dr H C Earl, who succumbed to a long illness on June 16th Having taken his medical degrees in Dublin University in 1886, he spent some years as assistant to the King's Professor of the Institutes of Medicine in his old school In 1897 he opened a clinical research laboratory, and thereafter practised exclusively as a clinical pathologist He was pathologist to the House of Industry Hospitals, and for a time to the Rotunda Hospital He became a Fellow of the Royal College of Physicians of Ireland in 1891 and served in several of the offices of the College Dr Earl had a sound knowledge of pathology, and his opinion carried great weight He was, outside his specialty, a man of wide reading and much culture, interested in art and literature He had a caustic wit, which failed to conceal a very kindly disposition. His companionable qualities, together with a very high sense of personal and professional honour, made him as much liked as he was respected by his medical colleagues

THE LATE DR J G G CORKHILL —The death took place at Birkdale on June 10th, in his sixty-fifth year, of Dr Joseph George Garibaldi Corkhill, physician to the Southport Smedley Hydropathic Establishment Dr Corkhill qualified as M R C S Eng in 1884 and graduated M D Manch in 1901, and M D Liverp in 1901 He was at one time chairman of the Southport Division of the B M A and of the Southport Medical Society, and was in practice in the district for many years, previously holding resident appointments at the Royal Infirmary and at the Stanley Hospital, Liverpool He was the author of several contributions to medical journals

THE LATE DR W A FULLER —Dr William Anderson Fuller, who died at Leeds on June 3rd at the age of 54, was the younger son of the late Lieut -Colonel Henry Fuller Receiving his medical education at Guy's Hospital, he qualified as M R C S Eng in 1898, and held house appointments at Huntingdon and Hastings. After a period as ship's surgeon in the East he took up practice at Milnthorpe, Westmorland, in 1905, taking over the practice of Dr G H Seagrave For the last 22 years of his life he worked in the village, in whose life he took a large part About two years ago he was made a justice of the peace for the county Dr Fuller married Miss Madge Seagrave, who survives him with one son and two daughters

---

CROYDON GENERAL HOSPITAL —Attention is being called to the pressing needs of this institution, extensions to which are to be opened by the King and Queen on June 25th The board of management have been compelled to borrow £30,000 from the bank, yet the enlargements do not include any increase in the number of beds Patients recovering from minor injuries have to be placed in lobbies and corridors, and serious cases turned away for lack of room The nurses also are inadequately provided for The present enlargement consists of an entirely new and comprehensive outpatients' department, with complete accommodation for casualties

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Pharmacists and the Shop Hours Acts.

AT the meeting of the Departmental Committee appointed by the Home Secretary to inquire into the working of the Shops (Early Closing) Acts, held on Thursday, June 16th, a letter was read from Mr. W. Huntrods, president of the Incorporated Society of Pharmacy and Drug Stores Proprietors of Great Britain, Limited. Mr. Huntrods stated that he had gone through the précis of evidence submitted to the Committee by the Retail Pharmacists' Union, with which taken as a whole he entirely agreed. Therefore, he did not think that it was necessary for him, along with other witnesses, to appear before the Committee in person. He would like, however, to supplement the views on a few points omitted in the precis referred to. Reference had been made to pharmacists, either registered or unregistered, being called upon to supply certain medicines, &c., after hours. He was firmly of the opinion that whilst this privilege should remain it should be confined to members of the Retail Pharmacists' Union and members of the Incorporated Society of Pharmacy and Drug Store Proprietors of Great Britain. On the other hand, he was desirous of pointing out that all necessary calls on pharmacy proprietors outside hours were infinitesimally few, and that in the event of a patient visiting a doctor in the case of sudden illness, the doctor had the prerogative of supplying the patient with the necessary medicine. He was firmly of the opinion that the shop closing hours should not be in any way extended, and he proposed that the closing hour on Saturday should be reduced at the least to the common level of the ordinary week-night closing hour—i.e., 8 o'clock. It was a well-known fact that the average working man finished his work approximately about noon on Saturdays, and had plenty of time to spend his money for necessities in two or three hours. He suggested that the closing hour on Saturday should not be allowed to exist as one hour longer than the ordinary closing hour, but should be one hour earlier—i.e., 7 P.M. Mr. Huntrods added that he presumed that it had been brought to the Committee's notice that there were many cases of sudden illness, and he would, therefore, re-emphasise the fact that the doctor had the prerogative under the National Health Insurance Act of supplying what was really necessary.

Tuberculosis in the Boot Trade.

At the same meeting of the Committee evidence was submitted by Messrs. H. Crabb and W. Orchard, representing the Joint Committee (Parliamentary) of the Retail-Bespoke, Making-Repairing Boot Trade (Employers and Employees). They stated that over 350,000 persons were engaged in the retail, bespoke, making, and repairing boot trades, and they desired on their behalf to place before the Departmental Committee the absolute necessity for the continuance of the general Early Closing Laws, subject to certain amendment, and asked that the present system of yearly renewals of the general Closing Order should be terminated and that the order should be made permanent, and should include within its scope boot-repairing establishments trading with the public direct. No one acquainted with the history of shop life would desire, they said, to return to the extremely bad conditions which obtained in the retail stores and shops of the boot trade up to comparatively recent years, when shops were kept open from 7.30 and 8 A.M. to 8.30 and 9 P.M. on Mondays, Tuesdays, Wednesdays, and Thursdays, and until 10 P.M. on Fridays, and 11 to 12 P.M. on Saturdays, and as the shop assistants and traders constituted a considerable portion of the community, it would be obvious that some attention should be given to the conditions of their hours of service to the public. As late as 1908–10 it was found as a result of an inquiry that working hours varied from 60 to 90 per week. The traders connected with the retail side of the industry were definitely in favour of the Early Closing Order, and would regret any modification of the existing orders which would have for its object the extension of or lengthening out the hours of service. On the health side of their appeal must be placed the demand for shorter hours. The trade was one in which boots, dusty and germ laden from the streets, came into direct contact with the worker. Consumption was rife amongst the operatives. Gastric troubles were numerous, also sickness, much of which was preventable. This constituted a considerable drain upon a business. The removal of night work after 7 or 8 P.M., concentration of services within the day periods, in the witnesses' opinion, would help to modify the inroads made upon the health of this portion of the community. Overwork and long hours produced unhealthy workers. Long periods in an unhealthy atmosphere sapped the vitality of the operatives. The National Union of Boot and Shoe Operatives handed into the Committee the following statistical table, showing the percentage of deaths due to tuberculosis among operatives in the trade from June, 1921, to December, 1926:—

	Number of deaths' and percentage		Number of deaths and percentage
June, 1921	77 (27·2)	June, 1924	69 (21·7)
December, 1921	64 (28·8)	December, 1924	61 (26·1)
June, 1922	82 (25·3)	June, 1925	72 (25·8)
December, 1922	46 (21·1)	December, 1925	47 (22·1)
June, 1923	54 (20·6)	June, 1926	63 (20·4)
December, 1923	51 (27·4)	December, 1926	45 (18·8)

Average 23·7.

It was stated by Mr. Orchard that his was the only organisation which had made a medical survey to ascertain the rate of consumption in their trade. He was a member of the executive body of the Boot Trade Benevolent Society, and they were faced with very considerable expense in making provision for the treatment of consumptive workers, which was the result of the conditions in the trade referred to in the evidence.

The Committee adjourned.

Audit (Local Authorities) Bill.

In the House of Commons on Wednesday, June 15th, on the motion for the second reading of the Audit (Local Authorities) Bill,

Mr. ARTHUR GREENWOOD moved a reasoned amendment in the following terms:—

> "That this House, being of opinion that the powers now vested in district auditors are anomalous and contrary to the principles of democratic government, declines to proceed with a Bill which fails to safeguard the rights of local elected authorities in the exercise of the duties imposed upon them by Acts of Parliament and the will of the community, indirectly increases the powers of bureaucratic officials independent of popular control, and establishes the principle that duly elected representatives of the people may be disqualified for holding office otherwise than for corruption, misconduct, or negligence, and notwithstanding that they retain the confidence of their constituents."

He said that the greatest objection to the measure was the constitutional one that it put extraordinary powers and penalties into the hands of the district auditor, and it put civil powers and penalties into the hands of the Minister of Health for the banishment from public life of his political opponents. The Bill was not merely a fussy interference with the rights of local authorities, but was really a blow at the development of social services by the local authorities, of a new attitude towards the people they employed, and an attempt to use the machinery of the State for party ends. That was bound to fail.

Miss SUSAN LAWRENCE seconded the amendment.

Mr. PALIN, in supporting the amendment, said he was surcharged 30 years ago as a Poor-law guardian because he voted for the provision of a little greenhouse in the workhouse grounds in order to supply flowers and plants for the hospital wards of the union infirmary.

Dr. SALTER said that he understood—he did not know whether it was true—that the district auditor had informed one borough council that at the next audit he was going to consider the question of the salaries of rate collectors and persons similarly employed, and he had indicated unofficially that he would probably surcharge in respect of the salaries of those rate collectors. What standard was he going to set? Certain borough councils paid extremely high salaries to their officials and poor wages to their workmen. The labour borough councils, on the other hand, had paid relatively high wages to the workmen. Those councils were to be surcharged, but what about the Tory borough councils that paid high salaries to their chief officials? He knew that in respect of the members of his own profession who were applicants for posts of medical officers of health, tuberculosis officers, assistant medical officers of health, and similar municipal offices if a labour borough council offered a salary of £800 per annum the Minister intervened and said: "That is not enough; you must pay more." The whole position at the present moment in regard to municipal administration was simply chaotic, and unless it was cleared up and simplified in a way that this Bill did not attempt to do the whole standard of public life in this country would be lowered and in particular they would drive out, or cause to retire from public life, a great many of the best type of administrators, men whom this country could ill-afford to lose.

On a division the amendment was rejected by 229 votes to 91 and the Bill was read a second time.

Poor-law Bill.

Mr. NEVILLE CHAMBERLAIN moved the second reading of the Poor-law Bill which, he said, was a monumental measure containing 245 clauses and 11 schedules. It was one of the largest pieces of consolidation work which had

owing to the adoption of more sensible clothing, and that had created a desire for physical fitness There they had the key to what could be done at a comparatively small cost. Advantage should be taken of all those forces which he had mentioned Education should be fostered and they should go on improving houses and the chances of those who were less well off to enjoy games and outdoor sports If all these things were done for ten years, and especially if health lectures were given all over the country, then not by fanatics preaching against the evils of this, that, and the other, but by people teaching what health meant, what good food meant, and what the disadvantages of alcohol really were as well as its advantages, they would appeal to the convictions of the people and get far greater success in any campaign for temperance than by the provisions of a Bill such as that before the House

The Earl of **ONSLOW** said that the Government were heartily in concurrence with the wishes of the supporters of the Bill, and were no less desirous than they were to secure judicious reform. They could not, however, at the present time assent to a measure which involved the reopening of the controversial question of the amendment of the licensing laws The report of the Southborough Committee on Disinterested Management was just out. It had only been in the hands of the Government a short time There were other matters connected with the licensing laws not dealt with in that report which it would be necessary to consider before any Government could give a pronouncement on the subject.

The debate was adjourned

HOUSE OF COMMONS.

WEDNESDAY, JUNE 15TH

Landlords and Vaccination of Tenants' Children

Mr **THURTLE** asked the Minister of Health if his attention had been drawn to a recent case in which a landlord obtained an order for possession of one of his dwellings on the ground that the tenant had failed to have one of his children vaccinated , and if he was prepared to amend the law in order to make it illegal for the vaccination of children to be a condition of any tenancy agreement.—Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied The answer to the first part of the question is in the affirmative and to the second part in the negative

Tuberculosis in North Wales

Sir **ROBERT THOMAS** asked the Minister of Health what were the returns of deaths from tuberculosis in North Wales for the years 1919 and 1926 , and whether the statistics showed an increase or a decrease upon the figures for the corresponding period before the war —Sir **KINGSLEY WOOD** replied The figures show a considerable diminution in the death rate from tuberculosis in each of the six counties in North Wales since 1911 The death-rate from tuberculosis in each administrative county and county borough appears in the Registrar-General's annual reports and statistical review, part I , for the years 1911–1925 The death-rates per million living for 1911, 1919, and 1926 in the six counties in North Wales are as follows —

—	1926	1919	1911
Anglesey	1448	1681	1787
Carnarvonshire	1661	2155	2216
Denbighshire	779	1206	1509
Flintshire	723	1052	1387
Merionethshire	1494	1910	2089
Montgomeryshire	979	1394	1318

Distilled Water in H M Ships

Sir **BERTRAM FALLE** asked the First Lord of the Admiralty whether each of H M ships in commission was fitted with an aeration plant for the aeration of distilled water supplied to the ships' companies for drinking purposes or whether the only aeration plants fitted in H M ships were those purchased by the various ships' companies for the purpose of manufacturing aerated fruit juice drinks —Lieut.-Colonel **HEADLAM** (Parliamentary Secretary to the Admiralty) replied The arrangements provided in H M ships for aerating distilled water before it is supplied to the ship's company for drinking purposes are as follows The delivery pipe from the distiller pump is led into a test tank and from thence the water gravitates into the storage tank In both tanks the water is aerated by spraying from the delivery pipe through a special rose into the tank

THURSDAY, JUNE 16TH

Medical Appointment at Dartmoor.

Mr **MONTAGUE** asked the Home Secretary how many prison hospital officers were offered promotion and did not accept the post of hospital principal officer at Dartmoor , how many declined , and the number against whom disciplinary action was taken involving forfeiture of promotion to this rank —Sir **WILLIAM JOYNSON-HICKS** replied The number of officers who declined the offer of promotion to this post at Dartmoor is three No question of disciplinary action arises, but one of the three officers who failed to give reasons satisfactory to his superiors will not in the ordinary course be considered again for such promotion

Inspection of Children's Homes

Mr **PETHICK-LAWRENCE** asked the Home Secretary what steps he proposed to take to implement the proposals of the Child Adoption Committee relating to the inspection of homes and institutions for poor children or young persons which were wholly or partly supported by voluntary contributions —Sir **WILLIAM JOYNSON-HICKS** replied . I propose to take these recommendations into consideration in connexion with other recommendations made by the Young Offenders' Committee which in both cases involve amendments of the Children Act, 1908

Pensioner and Refusal of Major Operation.

Mr **HARMSWORTH** asked the Minister of Pensions whether the refusal of a major operation was in any circumstances prejudical to a pensioner's claim for reassessment of his pension , whether, in a recent case the recommendation to operative treatment at Queen Mary's Hospital, Roehampton, was not regarded as restoring the Ministry's view of the pensioner's condition from the time of his previous operation in April, 1924, until November last year, when there was a reported recovery of 10 per cent , and whether he would cause a reinvestigation of the case in the light of the new evidence afforded by X ray examination and treatment in hospital —Major **TRYON** replied The penalty provided under Article 4 of the Warrant by way of direct reduction of pension would not be applied in such a case, but a claim to an actual increase of pension on account of an increase of disablement following on the refusal of a course of treatment, considered by my medical officers to be both advisable and reasonable, could not be admitted The condition which was found in hospital last month does not show that the assessment given in November and confirmed by the Medical Appeal Board in December was incorrect and there are no grounds for a reinvestigation

Local Authorities and Rural Housing

Mr **ROBINSON** asked the Minister of Health whether any proposals had yet been submitted by local authorities under the Housing (Rural Workers) Act , and in which counties were houses being reconditioned or extended to provide additional accommodation for workers in rural districts. —Mr **CHAMBERLAIN** replied Proposals have so far been submitted by 40 local authorities under the Housing (Rural Workers) Act, 1926 Other local authorities have schemes under consideration, but have not yet actually submitted proposals With regard to the last part of the question, statistics as to action taken under the Act are not yet available The following is the list —

County Councils —Cheshire, Cornwall, Cumberland, Derby, Devon, Dorset, Essex, Gloucester, Hereford, Kent, Lancashire, Lincoln (Holland), Lincoln (Lindsey), Middlesex, Northampton, Northumberland, Somerset, Stafford, Suffolk East, Surrey, Sussex East, Westmorland, Wiltshire, Worcester, Yorks East R , Yorks North R., Yorks West R , Anglesey, Brecknock, Carnarvon, Carmarthen, Denbigh, Montgomery, Monmouth, Pembroke

County Boroughs —Worcester

Rural District Councils —Aylsham R D C , Isle of Wight R D C , Smallburgh R.D C , Wayland R D C

London Lock Hospital

Lieut -Colonel **FREMANTLE** asked the Minister of Health if he had received complaints with regard to the management of the London Lock Hospital , if he was in a position to reassure the public on the subject , and, if not, in view both of the grants made to it by public authorities and of the national importance of the work which it undertook he would direct an inquiry to be made —Mr **CHAMBERLAIN** replied The hospital in question is a voluntary one and my hon and gallant friend will appreciate that the general management of voluntary hospitals does not come under my review Any grants to this hospital in respect of specific services are made by local authorities, principally by the London County Council I understand that the council have given notice of withdrawal of their grant in connexion with a general review of their arrangements for the venereal disease service, and I have concurred in their proposed action In these circumstances there seems no reason for any inquiry

Valvular Disease of the Heart among Soldiers

Dr **VERNON DAVIES** asked the Secretary of State for War the total number of soldiers invalided under the age of 21 years for valvular disease of the heart during each of the last five years for which statistics were available —

ever been attempted in this country, and he thought the gratitude of the general public, and particularly those concerned in the administration of the Poor-law, was due to the parliamentary counsel and the other ,officials who with extraordinary skill and with immense pains and labour had carried through the gigantic undertaking

The Bill was read a second time

PROTECTION OF ANIMALS AMENDMENT BILL.

On Friday, June 17th, the Protection of Animals (Amendment) Bill was considered in Committee (This measure amends the Protection of Animals Act, 1911, which makes it an offence to put down poison on land or buildings)

Dr **DRUMMOND SHIELS** moved two amendments, the first of which substituted for the word "vermin" which may under the Bill be destroyed by the laying down of poison in the interests of public health, agriculture, or the preservation of animals, the words "insects and other invertebrates, rats, mice, and other small ground vermin." He explained that on the second reading of the Bill he objected to the measure on the ground that the word "vermin" was too vague and injured wild birds especially He understood that the form in which he had moved the amendment was accepted by the promoters of the Bill The second amendment was to include wild birds among those which were to be safeguarded from poison

Both amendments were agreed to and the Bill passed through Committee

HOUSE OF LORDS.

TUESDAY, JUNE 21ST

LIQUOR (POPULAR CONTROL) BILL

THE House resumed the debate on the second reading of the Liquor (Popular Control) Bill, a measure which proposed to confer on boroughs of over 50,000 inhabitants and licensing districts the right of deciding periodically whether there is to be in their area "no change" in the present system of private ownership of the liquor trade, or whether the trade is to be reorganised under a system of public control on the lines adopted at Carlisle , or whether the sale of intoxicants in the area is to be prohibited

The Option of Prohibition

Lord **DAWSON** said that the most drastic proposal of the Bill was the option of prohibition. That was not necessary to the fabric of the Bill and was put in to satisfy the extreme temperance reformers who had made no secret of their intention to withhold their support from the measure if it did not contain that option. That fact alone would make him cautious about accepting a measure which presupposed that liquor was a poison and an accursed thing If it were adopted there would be no opportunity to go back if it turned out to be a mistake It might be too soon to say whether prohibition had been successful or not, but so far as it had gone they ought to be very cautious before they touched it in any way In countries where it had been adopted it had produced "bootlegging" and more drinking among the young than existed before A fresh view ought to be taken of the liquor question and the matter should be approached in a fresh way Duress was the curse of this Bill If they could, by common agreement, foster the influences which they knew were increasing temperance they would get a result in ten years which they would not get in a generation by any other means There was a serious danger of temperance reformers being the greatest obstacles to reform

Decrease in Drunkenness

There was ample evidence that the country was becoming more temperate They had only to go to the theatres, the cinemas, to the big restaurants, and to places of public resort on bank holidays to see that the amount of actual drunkenness was extremely small There was far less drunkenness in this country than in prohibitionist countries on the other side of the Atlantic. He had never seen, in recent years drunkenness of so terrible a character in this country as he had seen in prohibitionist countries The evidence with regard to disease due to alcohol showed a steady improvement, so much so that the provision that had to be made in the hospitals years ago were now found to be no longer necessary But there could be a great deal of harmful drinking without actual drunkenness and disease, and he was entirely with the supporters of the Bill in saying that there was too much drinking still and that they ought to set to work to hasten the movement towards greater temperance He could, however, give their lordships some encouragement. Let them consider a large and important section of the community, the people of moderate means, who gathered in popular restaurants possessing a full licence A full inquiry made three years ago showed that of the people who congregated in certain big restaurants 75 per cent. consumed no alcohol at all and of the 25 per cent. who did take drink, no less than three-quarters of them were drinking either light wine or beer, and only one-quarter consumed whisky or port That was a very striking testimony to the progress of temperance and of real sobriety He had made it his business, in view of this debate, to inquire whether those figures had become better or worse The answer was that in one restaurant the number of people who took liquor had gone down from 25 per cent to 17 per cent , and in another it had fallen to 7 per cent

The Habits of the Man under 35

In all investigations as to progress or otherwise of sobriety, it was the best and the fairest way to make a division between persons aged 35 and those under After 35 people's habits were formed, and if one became a drinker by that age he would very likely go on. What really mattered in this country was what people under 35 were doing He adopted that method in his next inquiry, which he made among the clerk class Taking the clerks over 40 he found that 21 per cent. were abstainers and 40 per cent. of those under 40 were abstainers That was quite in keeping with his own observations The clerk class in London, especially the younger ones, drank remarkably little If they turned to the army and asked any of the people responsible for the young soldiers, they would discover the same thing For instance, at Aldershot the young men came from their heavy drill in the morning about 11 30 or 12, and went, helter-skelter, to the canteen Five out of six of them went to the "dry" canteen, and only an infinitesimal number went to the "wet" canteen It was an interesting fact in regard to those who went to the "dry" canteen that they always asked for something sweet, showing that for the young sugar was a very good substitute for alcohol He asked some of his friends in the army recently, and they told him "It is absolutely true that the young soldier does not drink , you have only to look at him to see that." He had made it a point in the last few weeks to inquire among his business friends about drinking in business. It was quite true that it was far too rife It was an essentially damaging form of drinking, because it involved drinking on an empty stomach, as in the case of cocktail drinking, but it was decreasing and was far less prevalent than formerly He realised that in his inquiries he had not got down to the unskilled labour class, so he set to work, with some coadjutors, well qualified in finding out what people did and did not drink, because in any big hospital they got to know what an answer meant, whether it was "Yes" or "No" pretty quickly They went through the records of between 1500 and 1600 people of the unskilled labourer class The results were so striking and so much better than he expected that he handed the papers over to an actuarial friend to make something of them He (Lord Dawson) divided the total into abstainers, the temperate, and the imperfectly temperate He was up against the difficulty as to what to make the threshold of temperance He chose the figure 2, by which he meant to denote two drinks He took the standard of a pint of beer or one glass—not a full one—of whisky Taking the people under 35 and adding together the temperate people and the abstainers, they amounted to 90 per cent ; and the imperfectly temperate were 10 per cent. There was a change after 35, when the temperate people and the abstainers came to 71 5 per cent and the imperfectly temperate people to 28 5 per cent. Taking the abstaining people alone under 35 they were 51 per cent., and over 35 only 22 5 per cent.

It was open to people to say that the reason why there were fewer temperate people after 35 was that people grew into drink That was a fallacy People did not become drunken or intemperate once they had acquired temperance habits up to 35 It was comparatively rare for intemperance to break out after that age, except under stress of circumstances wholly outside the present considerations That gave food for thought and showed that our people were becoming steadily more sober and temperate in their use of alcohol It was really an outrage to call this country a non-sober country

The Desire to Keep Physically Fit

It was said that the diminution of drinking was due to restricted hours and higher prices He agreed that restricted hours promoted temperance He would support the continuation of the restriction of hours, provided that it was made uniform in all districts, but the influence of higher prices was not worth talking about Did a man stop drinking because he had no money ? He made his wife go without money If drink had got such a hold on him he would not stop because of the price What had produced the change to which he had referred was better housing for one thing, because directly they got better housing they got an improvement in respect to drinking The next fact was the increasing love of fresh air and the constant desire on the part of the people to be out in the country There was also the greater companionship of men and women, but he would put above all other considerations the great love of physical fitness at the present time Women had become more athletic owing to the adoption of more sensible clothing, and that had created a desire for physical fitness There they had the key to what could be done at a comparatively small cost. Advantage should be taken of all those forces which he had mentioned Education should be fostered and they should go on improving houses and the chances of those who were less well off to enjoy games and outdoor sports If all these things were done for ten years, and especially if health lectures were given all over the country, then not by fanatics preaching against the evils of this, that, and the other, but by people teaching what health meant, what good food meant, and what the disadvantages of alcohol really were as well as its advantages, they would appeal to the convictions of the people and get far greater success in any campaign for temperance than by the provisions of a Bill such as that before the House

The Earl of Onslow said that the Government were heartily in concurrence with the wishes of the supporters of the Bill, and were no less desirous than they were to secure judicious reform. They could not, however, at the present time assent to a measure which involved the reopening of the controversial question of the amendment of the licensing laws The report of the Southborough Committee on Disinterested Management was just out. It had only been in the hands of the Government a short time There were other matters connected with the licensing laws not dealt with in that report which it would be necessary to consider before any Government could give a pronouncement on the subject.

The debate was adjourned

HOUSE OF COMMONS.

Wednesday, June 15th.

Landlords and Vaccination of Tenants' Children

Mr Thurtle asked the Minister of Health if his attention had been drawn to a recent case in which a landlord obtained an order for possession of one of his dwellings on the ground that the tenant had failed to have one of his children vaccinated, and if he was prepared to amend the law in order to make it illegal for the vaccination of children to be a condition of any tenancy agreement.—Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) replied. The answer to the first part of the question is in the affirmative and to the second part in the negative

Tuberculosis in North Wales

Sir Robert Thomas asked the Minister of Health what were the returns of deaths from tuberculosis in North Wales for the years 1919 and 1926, and whether the statistics showed an increase or a decrease upon the figures for the corresponding period before the war—Sir Kingsley Wood replied The figures show a considerable diminution in the death-rate from tuberculosis in each of the six counties in North Wales since 1911 The death-rate from tuberculosis in each administrative county and county borough appears in the Registrar-General's annual reports and statistical review, part I., for the years 1911–1925 The death-rates per million living for 1911, 1919, and 1926 in the six counties in North Wales are as follows —

—	1926	1919	1911
Anglesey	1448	1681	1787
Carnarvonshire	1661	2155	2216
Denbighshire	779	1206	1509
Flintshire	723	1052	1387
Merionethshire	1494	1910	2089
Montgomeryshire	979	1394	1318

Distilled Water in H M Ships

Sir Bertram Falle asked the First Lord of the Admiralty whether each of H.M ships in commission was fitted with an aeration plant for the aeration of distilled water supplied to the ships' companies for drinking purposes or whether the only aeration plants fitted in H M ships were those purchased by the various ships' companies for the purpose of manufacturing aerated fruit juice drinks—Lieut.-Colonel Headlam (Parliamentary Secretary to the Admiralty) replied The arrangements provided in H M. ships for aerating distilled water before it is supplied to the ship's company for drinking purposes are as follows The delivery pipe from the distiller pump is led into a test tank and from thence the water gravitates into the storage tank In both tanks the water is aerated by spraying from the delivery pipe through a special rose into the tank

Thursday, June 16th

Medical Appointment at Dartmoor

Mr Montague asked the Home Secretary how many prison hospital officers were offered promotion and did not accept the post of hospital principal officer at Dartmoor, how many declined; and the number against whom disciplinary action was taken involving forfeiture of promotion to this rank—Sir William Joynson-Hicks replied. The number of officers who declined the offer of promotion to this post at Dartmoor is three No question of disciplinary action arises, but one of the three officers who failed to give reasons satisfactory to his superiors will not in the ordinary course be considered again for such promotion

Inspection of Children's Homes

Mr. Pethick-Lawrence asked the Home Secretary what steps he proposed to take to implement the proposals of the Child Adoption Committee relating to the inspection of homes and institutions for poor children or young persons which were wholly or partly supported by voluntary contributions—Sir William Joynson-Hicks replied I propose to take these recommendations into consideration in connexion with other recommendations made by the Young Offenders' Committee which in both cases involve amendments of the Children Act, 1908

Pensioner and Refusal of Major Operation

Mr Harmsworth asked the Minister of Pensions whether the refusal of a major operation was in any circumstances prejudical to a pensioner's claim for reassessment of his pension, whether, in a recent case the recommendation to operative treatment at Queen Mary's Hospital, Roehampton, was not regarded as restoring the Ministry's view of the pensioner's condition from the time of his previous operation in April, 1924, until November last year, when there was a reported recovery of 10 per cent, and whether he would cause a reinvestigation of the case in the light of the new evidence afforded by X ray examination and treatment in hospital—Major Tryon replied: The penalty provided under Article 4 of the Warrant by way of direct reduction of pension would not be applied in such a case, but a claim to an actual increase of pension on account of an increase of disablement following on the refusal of a course of treatment, considered by my medical officers to be both advisable and reasonable, could not be admitted The condition which was found in hospital last month does not show that the assessment given in November and confirmed by the Medical Appeal Board in December was incorrect and there are no grounds for a reinvestigation.

Local Authorities and Rural Housing

Mr Robinson asked the Minister of Health whether any proposals had yet been submitted by local authorities under the Housing (Rural Workers) Act, and in which counties were houses being reconditioned or extended to provide additional accommodation for workers in rural districts.—Mr Chamberlain replied· Proposals have so far been submitted by 40 local authorities under the Housing (Rural Workers) Act, 1926 Other local authorities have schemes under consideration, but have not yet actually submitted proposals With regard to the last part of the question, statistics as to action taken under the Act are not yet available. The following is the list —

County Councils—Cheshire, Cornwall, Cumberland, Derby, Devon, Dorset, Essex, Gloucester, Hereford, Kent, Lancashire, Lincoln (Holland), Lincoln (Lindsey), Middlesex, Northampton, Northumberland, Somerset, Stafford, Suffolk East, Surrey, Sussex East, Westmorland, Wiltshire, Worcester, Yorks East R, Yorks North R, Yorks West R, Anglesey, Brecknock, Carnarvon, Carmarthen, Denbigh, Montgomery, Monmouth, Pembroke

County Boroughs—Worcester

Rural District Councils—Aylsham R.D C, Isle of Wight R D C, Smallburgh R.D C, Wayland R D C

London Lock Hospital

Lieut.-Colonel Fremantle asked the Minister of Health if he had received complaints with regard to the management of the London Lock Hospital, if he was in a position to reassure the public on the subject; and, if not, in view both of the grants made to it by public authorities and of the national importance of the work which it undertook he would direct an inquiry to be made—Mr Chamberlain replied The hospital in question is a voluntary one and my hon and gallant friend will appreciate that the general management of voluntary hospitals does not come under my review Any grants to this hospital in respect of specific services are made by local authorities, principally by the London County Council. I understand that the council have given notice of withdrawal of their grant in connexion with a general review of their arrangements for the venereal disease service, and I have concurred in their proposed action In these circumstances there seems no reason for any inquiry

Valvular Disease of the Heart among Soldiers

Dr Vernon Davies asked the Secretary of State for War the total number of soldiers invalided under the age of 21 years for valvular disease of the heart during each of the last five years for which statistics were available—

Commodore **DOUGLAS KING** replied The information is as follows —

Year	Total No discharged	No under 21 years of age
1923	90	34
1924	139	50
1925	139	48
1926	101	37
1927 (to date)	29	10

Typhoid Fever in Gravesend District

Mr **DAY** asked the Minister of Health the number of typhoid fever cases notified during the recent outbreak in the Gravesend district, and whether a representative of the Ministry had visited the town —Mr **CHAMBERLAIN** replied Thirty-nine cases of this disease have been notified in the borough of Gravesend during the past five weeks *The answer to the last part of the question is in the* affirmative

MONDAY, JUNE 20TH

Heart Disease in the Air Force

Dr **VERNON DAVIES** asked the Secretary of State for Air if he could give the number of discharges from the Royal Air Force for heart disease for the years 1921 to 1927, the number of such cases under 21 years of age, and the number of cases in which a history of rheumatism was obtained —Sir S **HOARE** replied The following table gives the information requested —

Discharges from the Royal Air Force for Heart Disease (Organic)

Year	Total discharges for valvular and other diseases of the heart	Under 21 years of age	
		With definite history of rheumatism	Other cases
1921	16	1	5
1922	17	5	4
1923	15	4	7
1924	14	6	0
1925	10	5	0
1926	14	2	2
1927 (to date)	8	0	2

These figures do not include 90 cases of heart disease (of which 23 were valvular) who were invalided by the Discharge Board in 1921, but who, from the fact that this was a post-war clearance of medical unfits, probably did not include any under the age of 21 The cases in the third column are those in which, from a scrutiny of individual records, a history of "rheumatism" was obtained

Ex-Service Men and Tuberculosis

Mr **GROVES** asked the Minister of Pensions whether he would consider the issuing of instructions to local tuberculosis medical officers that when ex-Service tuberculosis patients were recommended for a course of convalescent treatment at Douglas Homes, they should be kept on treatment allowances —Lieut -Colonel G F **STANLEY** replied The Homes referred to are not an institution approved by the Ministry of Health for in-patient treatment Men staying in these Homes are not, therefore, eligible for the allowances attaching to this form of treatment

Provision of Open Spaces and Playing Fields

Sir **ROBERT THOMAS** asked the Home Secretary whether he was prepared to introduce legislation to provide that public parks and squares which had sufficient area for playing fields should be thrown open for the benefit of the youth of the country —Sir **KINGSLEY WOOD** replied There are already powers in the general law, which are freely used, by which local authorities may set aside parts of public open spaces under their control for playing purposes, and my right hon friend has every reason to think that local authorities generally fully appreciate the need for playing fields

Medical Research Council and Dogs Act, 1906

Dr **VERNON DAVIES** asked the Home Secretary if he proposed to give effect to the unanimous recommendation of the Medical Research Council contained in Cmd 2880 that Section 3 (5) of the Dogs Act, 1906, should be repealed —Sir W **JOYNSON-HICKS** replied This recommendation has not yet been considered by the Government

Maisons Tolerées at Shanghai

Mr **PETHICK-LAWRENCE** asked the Secretary of State for Foreign Affairs whether he was aware that the Chinese were complaining that girls of 15 years of age were being introduced into masions tolerees for the soldiers in the international area at Shanghai, and whether [illegible] t [illegible] action in the matter —Mr **LOCKER-LAMPSON**, Under Secreta
Foreign Affairs, replied H M Consul-General at Sh
telegraphs that, so far as he and the Shanghai Mu
Police have been able to ascertain, there is no foun
whatever for this report All remaining licences for
of ill-fame in the International Settlement were with
on Dec 31st, 1924, by order of the municipal council.

aining of Mental Defectives —A lecture ed Training Defective Children to Become Useful ns will be given by Dr Maria Montessori in aid of Royal Free Hospital Centenary Fund at the Æolian , Bond-street, London, W 1, on Tuesday, July 5th, 15 p m Lady Barrett will take the chair Tickets are able from the Æolian Hall Box Office or from the on (R F H) School of Medicine for Women, 8, Hunter- , W C 1

ing Edward's Hospital Fund for London — pecial committee appointed to inquire into the question y beds at voluntary hospitals has begun to receive ce The members of the committee are Viscount eden (chairman), Sir John Rose Bradford, P R C P, ernard Mallet, Mr V Warren Low, F R C S, and Winifred Cullis All communications should be ed to the secretary of the Fund, G P O Box 465a, brook, E C 4

yal Westminster Ophthalmic Hospital — rsday, June 30th, at 4 p m, the Duke of Connaught y a commemoration-stone in the entrance hall of the building now rising in Broad-street, Bloomsbury the ceremony a reception will be held in the out- consulting room of the new building, which is as y one story in height It is hoped that it will be or occupation by March 25th, 1928, when the present in King William-street, Strand must be vacated

pital and a Penny Fund —Three years ago y fund was started in connexion with the Victoria l at Lewes The number of subscribers last year proximately 3400, and the amount received in sub- ons was £785 After paying expenses and the cost of nt of subscribers in hospitals at Brighton, £769 was over from the fund towards the hospital's expenses ted that the institution has received £2512 7s 11d ovember, 1923

Infirmary for Dewsbury —On June 18th ndation stone of a new infirmary for Dewsbury and was laid by Sir Mark Oldroyd, whose contribution building fund amounts to £13,000 The scheme will ,000, and towards this sum £28,000 has been from the sale of the old infirmary and £21,000 n subscribed by local effort The new infirmary e accommodation for 100 beds and a nurses' home of 50

al Medical Benevolent Fund —The following e additional cases relieved at the last meeting —

, aged 54, of M R C S who died in 1925 When her band's estate is settled she expects to receive about week At present living on capital Has been living ds for some time, but now has a room the rent of which week Voted £10

aged 65, of F R C S who died in 1912 At present is ks for expenses to go to a convalescent home Total 60 per annum Voted £5

, aged 70 of L R C P who died last month Late l was an annuitant of the Fund Applicant only has Age Pension Voted £26 in 12 monthly instalments

iptions may be sent to the Treasurer, Sir Charters ds, at 11, Chandos street, Cavendish square, London,

ial Medical Benevolent Fund of Ireland — annual meeting of this Fund was held at Dublin on 16th, Dr Bethel Solomons in the chair It was stated the number of grants made during the year was 81, mount disbursed amounting to £1702 1s 8d During ear the Fund lost several friends and subscribers, he committee is making an appeal for wider support profession

University of Manchester —Dr A W Downie has been appointed lecturer in bacteriology, and Dr J M Yoffey demonstrator in anatomy

University of Durham —In the third examination for the M B, B S degree held recently, R S Holcombe satisfied the examiners in Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Public Health, and Medical Jurisprudence, and Maurece Lees and J H F Pankhurst were approved in the same subjects with the addition of General Principles of Therapeutics

University of Geneva —A holiday course for candidates in medicine, surgery, and the specialties is to be held at Geneva from Sept 5th to 30th Information can be obtained from the secretariat of the University

International Medical Post-Graduate Courses A series of post-graduate courses will be held at Berlin between Sept 15th and Oct 31st under the auspices of the Kaiserin-Friedrich-Haus, 2–4, Luisenplatz, Berlin, N W 6 Particulars will be supplied on application

Dr Robert de la Poer Beresford, J P, medical officer of health for the urban and rural districts of Oswestry, has resigned this office after 54 years' service

Royal East Sussex Hospital —It has been decided to proceed at a cost of £5500 with the provision of an orthopædic department The scheme will also include an isolation ward

Derby Poor-law Hospital —The Derby guardians proposed to build a new hospital at a cost of £120,000 The Minister of Health has, however, declined to sanction the expenditure of more than £80,000, on the ground that insufficient reason has been shown for proceeding with the larger scheme

Herefordshire General Hospital —This institution is to be enlarged at an estimated cost of £64,000, which is to be provided by the sale of its securities A special appeal for money is, however, to be made The hospital's recently established contributory scheme has been well received and is making good progress

Central London Throat, Nose, and Ear Hospital —At the annual meeting last week it was stated that about half of the £35,000 required for the new wing has still to be raised, and that the in-patient pressure is constantly increasing The wing will provide increased facilities for training specialists in the post-graduate medical school, which has already sent out 1432 students

Enlargement of Leeds Maternity Hospital In 1905 this institution began as a small nursing home with six beds, five years later it was enlarged, and last year 25 per cent of the Leeds babies were born there The pressure has now become so great that the number of beds is to be increased from 75 to 102 A new wing is to be added on each side of the central block, and a new out-patients' department provided, together with an isolation block and a new operating theatre

Extension of Louth Hospital —Princess Helena Victoria has opened an extension of the Louth and District Hospital which, it is claimed, will place the neighbourhood in possession of hospital facilities not usually available in a town of less than 10,000 inhabitants The former 36 beds have been increased to 56, and the extension consists of a maternity ward, a children's ward, an X ray department, accommodation for a larger nursing staff, and a doctors room, there are two private maternity wards

Newton Abbot Hospital Visit of the Prince of Wales —During his visit to the West of England last week the Prince of Wales opened a new wing of Newton Abbot Hospital and Dispensary, the second hospital in England to be endowed with a stock of radium. The new wing, which is to be especially devoted to the treatment of cases of cancer, includes eight private wards, further accommodation for nurses, considerable enlargement of the men's and women's wards, and their division into surgical and medical wards, and the conversion of the old dispensary into ophthalmic and dental departments

Medical Tour to Italian Spas —A visit of medical men to Italian spas and climatic resorts is being arranged for next September The party will be accompanied by English-speaking Italian doctors and the tour will be made by special train Among the places included in the itinerary are Rome, Naples, Agnano, Capri, Sorrento, Fiuggi, Messina, Taormina, Palermo, and Montecatini Ladies may join the party, but only a limited number of applicants can be accommodated Further information is obtainable from the Italian State Tourist Office, 16, Waterloo-place, Regent-street, London, S W 1

ROYAL FREE HOSPITAL CENTENARY APPEAL —The Old Bloomsbury Revels and Market will be held at the Foundling Hospital, Guildford-street, London, W C, from 2 P M on June 23rd, 24th, and 25th, for the benefit of this Appeal A Handel Concert will be given at 5 30 P M on each day, when the London Chamber Orchestra will play and a scena from the opera "Julius Cæsar" will be produced by Mr Nigel Playfair Further particulars may be obtained from the organiser of the Appeal at 170 Piccadilly, London, W 1

MEDICAL GOLFING SOCIETY —The annual summer meeting was held on June 10th at Walton Heath where competitors were the guests of Lord Riddell There were over 100 entries The competition results were as follows THE LANCET Challenge Cup, H T P Kolesar, Henry Morris Challenge Cup E Playfair, Milsom Rees Challenge Cup V E Negus Handicap results were —Class I First Prize, Sir Kenneth Goadby tied with A W Soper, Best Last Nine, H D Gillies Class II First Prize, H A Chodak Gregory tied with G Dawson, Best Last Nine, H L Hatch Foursomes were won by J O'Malley and W A Tindal Atkinson

IRISH MEDICAL ASSOCIATION —The annual meeting of this association was held on June 16th at Dublin, the President, Dr F C Purser, and subsequently Dr H T Warnock, presiding The report of the Council and the financial statement for the year were read and approved The membership on Dec 31st, 1926, was 415, and the subscriptions paid during the year amounted to £535 10s The results of the election of the officers and Council were read Dr Hugh T Warnock, of Donegal, and Mr P E Hayden of Dublin, were unanimously elected President and Vice-President respectively A discussion took place with reference to the promotion of Poor-law medical officers, and a resolution was carried, asking the Minister for Local Government and Public Health to refuse his sanction to any promotion unless he was satisfied that it was being made on proper grounds A further resolution was carried demanding that the rates of remuneration of registrars of births, deaths, and marriages should be raised to the level of the fees payable in England A long discussion followed on the status and emoluments of county hospital surgeons A resolution was carried demanding that the salary of whole-time county hospital surgeons should be not less than £1000 a year

RADIUM TREATMENT AT UNIVERSITY COLLEGE HOSPITAL —Dr A E B Paul, Harker-Smith Registrar to the hospital, has compiled a report of the results of radium treatment in the hospital, with special reference to carcinoma of the cervix and menorrhagia The report is divided into five parts Part 1 gives a "follow up" of the results to Oct. 31st, 1926, of all cases of carcinoma of the cervix, carcinoma of the uterine body, and one case each of carcinoma of the vulva and sarcoma of the vagina which were treated with radium from 1921 to October, 1925 Part 2 gives the results of treatment for menorrhagia, fibroids, and dysmenorrhœa since November, 1924, and Part 3 the cases of carcinoma of the cervix and uterine body treated for the first time with radium between Oct 31st, 1925, and Oct 31st, 1926 Part 4 gives results of cases of menorrhagia (menopausal and essential), fibroids, dysmenorrhœa, and cervicitis treated for the first time between Nov 1st, 1925, and Oct 31st, 1926, and Part 5 deals with various recent isolated cases Of the 62 inoperable cases of carcinoma of the cervix discussed in Part 1, four could not be traced Of the remaining 58, 52 are dead, the average length of life from the date of the first treatment being 15 months Three cases are alive and have no clinical signs of recurrence after 25, 24, and 20 months respectively The other three cases still alive have recurrences 40, 17, and 16 months after first radiation Dr Paul states that it has been repeatedly noted that the treatment has rendered the patient more comfortable, especially as regards the lessening of hæmorrhage, and in many cases the alleviation of pain Out of 13 operable cases of carcinoma treated with radium only seven are alive and have no recurrence at the end of 13, 40, 29, 24, 22, and 12 months respectively, and one case is alive after 47 months, but has a recurrence With regard to non-malignant cases, the results of treatment by radium in cases of menopausal hæmorrhage are said to be extremely good, only a very few cases requiring a second dose The usual dose now given is 3000 to 3600 mg -hours of the salt, and the technique of plugging the cervical canal as well as the vagina is now standard practice The results of radium when used in *cases of* essential menorrhagia are also encouraging Cases of fibroids vary much as regards results, out of 20 cases first treated over one year ago, 12 have shown good results as regards the cessation of hæmorrhage, three requiring further doses before this was attained

Notes, Comments, and Abstracts.

SUPPORT FOR THE SEDENTARY.

THERE was once a time (if biologists are to be believed) when our ancestors ran about on all fours The habit was then fashionable, and it is not for us to blame them, it would be impious to disinter the family skeleton merely to mock at it All the same, it was certainly a change for the better when the function of support was relegated to the hind limbs, and at a small sacrifice of speed and steadiness two sensitive hands were given their freedom To the untrammelled activity of our fingers we owe, perhaps, the most of our intellectual development—a thesis ably maintained by Prof F Wood Jones in his book, "Arboreal Man"—and the advantages of bipedal transport must be obvious to anyone who gives a moment's thought to the relative efficiency, in modern social circles, of the horse's hoof and the human hand.

A great deal has been written about man's assumption of the erect posture; its benefits have been set out at length in scientific literature, and its regrettable effect on the abdominal organs has been freely ventilated of late years in the daily newspapers It seems the more astonishing, therefore, that but little attention has been paid to another profound biological adaptation that is taking place in our midst Our quadruped forefathers, it must be supposed, needed long persuasion by the forces of nature before they would trust themselves to the sole support of two hind feet, and many ages have gone by since this momentous adjustment was completed Yet in a few short years a large proportion of the human race—and those which were most highly developed—have been carelessly converted into sedentary animals, and hardly anyone seems to have noticed that this can be regarded as the beginning of a fundamental change in our anatomical evolution At first (as we have remarked) man supported himself on four feet, then he relied on two, and now, in London at any rate, he supports himself, whenever possible, upon his back or the lower part of it. From being a biped—which was really not unsatisfactory—he has become, so to speak, a binate Should this change go on much further, it will mean the release of a second pair of limbs from the bondage imposed by stability; but unfortunately the strenuous service of our feet throughout the centuries has somewhat impaired their flexibility, and we cannot look forward with any certainty to having descendants with four hands in everyday use.

It is not suggested, of course, that the change described is as yet complete, even those of us who daily spend eight and a half hours lying down and 15 hours sitting up are by no means incapable of movement on the legs, we remain facultative bipeds though primarily binatile. Even now there are but few people whose legs are wholly functionless, for one thing it is hard to arrange mechanical transport for every sort of journey, for another, we are as yet too ill-adjusted to our environment to dispense with artificial exercises of the limbs and trunk. Nevertheless, the amount of movement which is possible for the average office-worker is so small that it is of very real importance how he sits and what he sits on. The havoc wrought in the abdomen by man's becoming erect is nothing to what is being done by his collapse into a spineless curve

To those who spend much of their days in walking or riding on horses it does not matter much how the body is disposed at other times, it may be allowed to take up a position of full relaxation in the easiest chair that the wit of man can devise. It is otherwise, however, with the person whose fatigue springs not from exercise but from the lack of it—whose spinal and abdominal muscles have lost their tone from general lethargy and from disuse With such a person, when at sedentary work, an attempt should be made to break the sagging habit True cure can only be brought about by bringing back muscular tone and well-being, but this does not mean that no support to the back is permissible Properly planned, a chair may do much not only to prevent the bad posture which springs from fatigue, but also to overcome it The muscle which is regaining tone cannot be expected to keep the back straight for long periods unaided, and its owner requires *constant* reminders from his chair if he is to make the conscious efforts which are needed for its re-education

Most ordinary chairs, in spite of the time to be spent in them, are made so unwisely that the tired body can only find rest by falling forward into a bad position Recognition of this fact has led the Rev. W A. Simcox (of Sunnycroft Forest Corner, Ringwood) to devise a new model which he calls the Convex Health Chair and which he strongly recommends for general use Where the backs of many chairs are concave, to fit the curve of the relaxed shoulders, the back of Mr. Simcox's chair is convex, so that from the lumbar region upwards the spinal column remains more or less in contact with the chair, but the shoulders get no support unless they are thrown backwards, their roundness being thus corrected To the person who sits back on this chair there is a perpetual encouragement to place the body in a good position, thus incidentally increasing the depth of respiration, and the feeling of support is compensation for the lack of soft repose Unfortunately, however, it remains possible to sit on the front of the chair and ignore the back altogether, so that the spine droops and the shoulders fall forwards, and Mr Simcox's design for this reason does not wholly solve the problem presented by the person who sits writing at a table, for whom an adjustable chair, offering support at the lumbar curve alone, is probably the ideal As furniture for a dining room or living room, Mr Simcox's model has much to recommend it, however, and experiments of this kind are worth the serious consideration of all who realise how much damage is done by chairs which connive at deformity instead of persuading into rectitude If we are to live in our chairs let us at least have them habitable

GOLD COAST HEALTH REPORT

A REPORT, prepared by Mr G C du Boulay, acting Colonial Secretary, on the affairs of the Gold Coast for 1925–26, has been issued by the Colonial Office From the medical and sanitary section some interesting particulars are gathered, registration of births and deaths is compulsory in 19 towns The number of births registered in 1925–26 was 2914, and of deaths 3811 There were 142 stillbirths The chief causes of death were, as usual, pulmonary and intestinal diseases The number of European residents was 3104, of whom 994 were officials, 1529 merchants, 469 miners, and 112 missionaries Among them there were 22 deaths, whilst the invaliding rate averaged 10 27 per 1000 The eight deaths amongst European officials were due to septicæmia (2), blackwater fever (1), heart failure (1), drowning (1), chronic alcoholism (1), hepatitis (1), and suicide (1) Of the 14 deaths amongst European non-officials 3 were due to blackwater fever, 3 to malaria, 2 to dysentery, and 1 each to intestinal obstruction, fractured spine, yellow fever, perforated duodenal ulcer, drowning, and amœbic abscess of liver The total population, at the census taken in 1921, was approximately 2,296,400 Outbreaks of epidemic disease occurred during the year in various places Eight cases of yellow fever were reported —viz, four cases at Accra, two at Nsawam, and one each at Winneba and Cape Coast Extensive outbreaks of smallpox occurred in Ashanti and the Northern Territories 311,927 vaccinations were performed, of which 98,869 were reported as successful, giving a percentage of 31 69 The efforts of the medical and sanitary authorities in promoting the treatment of disease and the knowledge of general hygiene continue to exercise a beneficial effect on the general health of Europeans Most of the large towns were in a fairly satisfactory sanitary condition 405,228 houses were inspected during the year and the average larval index was 0 78 per 100 The drainage of Saltpond Lagoon—a long-needed sanitary measure—was commenced The congested area at Cape Coast, which was demolished in 1924–25, was laid out and drained At Kumasi, in Ashanti, a temporary market, new wells, and a number of sanitary structures were provided At Accra the mean shade temperature was 79 1°, and at Kumasi and Sekundi 79° and 80° respectively

The rainfall was at Accra 36 54 inches, at Aburi 57 22, at Sekundi 43 71, at Axim 69 41, at Tarkwa 59 11, at Kumasi 67 24, and at Tamale 45 77 The climate, though hot and damp, is cooler than that of most tropical countries situated in the same latitude It is not in itself unhealthy, but an evil reputation has been earned for it in the past by the prevalence of mosquito-borne diseases, against which all possible precautions have constantly to be taken The Gold Coast is peculiarly free from any of the discomforts associated with tropical countries, hot nights and intense heat by day are the exception rather than the rule, while insects are comparatively unobtrusive The rainfall varies with the configuration of the country The first rains, or rainy season proper, begin in March and end in July, the later rains are spread over the months of September and October The rainy season is marked by a considerable fall in the temperature, which is found to be refreshing to many Europeans, but proves trying to some There are eight European hospitals, 27 African hospitals, and one infant welfare hospital During the year 3174 Europeans and 94,736 Africans were treated in the hospitals and dispensaries of the colony The daily average number of patients in the Accra Lunatic Asylum was 227 1 There were 49 deaths—48 males and one female

The Gold Coast is divided into three parts—Gold Coast Colony, area 23,490 square miles, Ashanti, area 24,560 square miles, and the Northern Territories, area 30,600 square miles To this is now added the narrow strip of Togoland—area 13,040 square miles—administered by the Gold Coast Government under the Mandate allotted to Great Britain by the Peace Treaty

HOW TO REMAIN YOUNG.

THE preoccupation of the elderly with the idea of becomin young again appears to be one of the dominating themes a the present day in the emotional life of civilised communitie The space given to attempts at rejuvenation in the popula press reflects to some extent the general interest in th subject Hence a popular book called "Outwitting Middle Age,"[1] by Mr Carl Ramus, a surgeon in the U S Public Health Service, ought to have a wide appeal The title is somewhat misleading, however, for the book is really concerned with preserving comfortable middle age and preventing the onset of senile decay It is strongly provocative in places, dealing with such debatable subjects as Steinach's operation, historical cases of great longevity and some aspects of the diet problem, but it is certainly interesting throughout even if its by-paths into the subconscious mind and psycho-analysis seem a little too far from the beaten track A good bibliography is included so that anyone to whom old age is a dreaded nightmare can obtain quite a lot of information as to how its arrival may be postponed or prevented.

TRAINING WORKING GIRLS IN HUNGARY

THOSE interested in the work of the "Save the Children" Fund will remember Mme Julie Eve Vajkai's booklet "Child Saving and Child Training" Her latest book "Education for Life,"[2] is a further fascinating account of her work-schools in Budapest She started with a random collection of girls in some old military huts, under the most heart-rending conditions of after-war poverty and distress After a desperate struggle to find handicrafts which they could learn quickly and make money by, she has at last succeeded in establishing her schools firmly enough to be able to bring education into first place and relegate earnings to second Her one aim is to prepare the children in the best possible way for their future, which is the work-room or factory, and her success is due to her skill in estimating the creative capacity of her individual pupils and grading their instruction accordingly, so that they always have, from the start, the stimulus of successfully achieving something useful Her girls have received glowing praise from employers all over Hungary for their productiveness, enthusiasm, and adaptability For instance, an electric lamp manufacturer employed some girls who had learnt to make pillow-lace at the school, and was amazed at the speed with which they picked up the totally different technique of his own trade Her secret lies in knowing how to train girls to like work, self-government and team-work is carried to a perfection rarely seen even in this country This experiment now includes nine work-schools and a reformatory, but of greater importance than the immediate work is the interest it has aroused in the Government and the Association of Hungarian Manufacturers There is, indeed, a fair prospect that it may lead to a wholesale and salutary reform in the spirit not only of the national education, but also of the national industry

MEDICAL TREATMENT OF GLAUCOMA

FOR some years Dr Charles Abadie has held that glaucoma is due to disturbance of innervation of the ocular sympathetic, giving rise to an exaggerated dilatation of the vessels of the eye and consequently to hypersecretion of intra-ocular fluids and an increase of tension He therefore treats the condition with vasoconstrictor drugs[3] and claims good results from the combined administration of 1 5 to 2 0 mg of adrenalin (according to the age and weight of the patient), a cachet of 0 1 to 0 2 g of ergotin, and 1 to 2 g of calcium chloride in aqueous solution So far, according to Dr Abadie, this treatment has been found beneficial in every case he has treated Not only is the glaucoma relieved or its development hindered, but there is a considerable gain in visual acuity, especially in the early stages

So long ago as 1897 Abadie brought forward a theory of glaucoma according to which the hypertension depended on a vascular disturbance Subsequently he suggested operation on the ciliary nerves It has been found that removal of the superior cervical ganglion is followed by decrease of intra-ocular pressure, but the effect is only temporary

The theory of hypersecretion as the cause of glaucoma does not tally with the generally held opinion which ascribes it to a blockage in the channels of exit of the intraocular fluid, nor with the theory recently put forward by Dr Duke Elder (see THE LANCET, June 11th, p 1250), who combats the view that true secretion takes any part in its formation at all
